January 24, 2008

Abstract

We investigate modified steepest descent methods coupled with a looping Kaczmarz strategy for obtaining stable solutions of nonlinear systems of ill-posed operator equations. We show that the proposed method is a convergent regularization method. Numerical tests are presented for a linear problem related to photoacoustic tomography and a non-linear problem related to the testing of semiconductor devices.

Keywords. Nonlinear systems; Ill-posed equations; Regularization; Steepest descent method; Kaczmarz method.

AMS Classification: 65J20, 47J06.

1 Introduction

In this paper we propose a new method for obtaining regularized approximations of systems of nonlinear ill-posed operator equations.

The inverse problem we are interested in consists of determining an unknown physical quantity $x \in X$ from the set of data $(y_0, \ldots, y_{N-1}) \in Y^N$, where $X, Y$ are Hilbert spaces and $N \geq 1$. In practical situations, we do not know the data exactly. Instead, we have only approximate measured data $y^\delta_i \in Y$ satisfying

\[ \|y^\delta_i - y_i\| \leq \delta^i, \quad i = 0, \ldots, N - 1, \tag{1} \]

with $\delta^i > 0$ (noise level). The finite set of data above is obtained by indirect measurements of the parameter, this process being described by the model

$$F_i(x) = y^i, \ i = 0, \ldots, N - 1,$$

where $F_i : D_i \subset X \to Y$, and $D_i$ are the corresponding domains of definition.

Standard methods for the solution of system (2) are based in the use of Iterative type regularization methods [1, 7, 13, 16, 19] or Tikhonov type regularization methods [7, 23, 30, 33, 32] after rewriting (2) as a single equation $F(x) = y$, where

$$F := (F_0, \ldots, F_{N-1}) : \bigcap_{i=0}^{N-1} D_i \to Y^N$$

and $y := (y^0, \ldots, y^{N-1})$. However these methods become inefficient if $N$ is large or the evaluations of $F_i(x)$ and $F_i'(x)^*$ are expensive. In such a situation, Kaczmarz type methods [6, 15, 22, 25] which cyclically consider each equation in (2) separately are much faster [26] and are often the method of choice in practice.

For recent analysis of Kaczmarz type methods for systems of ill-posed equations, we refer the reader to [4, 10, 11, 17].

The starting point of our approach is the steepest descent method [7, 29] for solving ill-posed problems. Motivated by the ideas in [10, 11], we propose in this article a loping Steepest-Descent-Kaczmarz method (I-SDK method) for the solution of (2). This iterative method is defined by

$$x^\delta_{k+1} = x^\delta_k - \omega_k \alpha_k s_k,$$

where

$$s_k := F'_k(x^\delta_k)^* (F_k(x^\delta_k) - y^\delta_k),$$

$$\omega_k := \begin{cases} 1 & \|F_k(x^\delta_k) - y^\delta_k\| \geq \tau \delta_k \\ 0 & \text{otherwise} \end{cases},$$

$$\alpha_k := \begin{cases} \Phi_{\text{rel}} \left( \|s_k\|^2 / \|F'_k(x_k^\delta) s_k\|^2 \right) & \omega_k = 1 \\ \alpha_{\text{min}} & \omega_k = 0 \end{cases}.$$
If $M$ is an upper bound for $\|F'_{[k]}(x)\|$, then $\|s_k\|^2/\|F'_{[k]}(x_k^δ)s_k\|^2 \geq 1/M^2$ (cf. Lemma 3.2). Hence the relaxation function $\Phi_{rel}$ needs only be defined on $[1/M^2, \infty)$. In particular, if one chooses $\Phi_{rel}(s) = \alpha_{\min} \leq 1/M^2$ on that interval, then $\alpha_k = \alpha_{\min} \leq 1/M^2$ and the l-SDK method reduces to the loping Landweber-Kaczmarz (l-LK) method considered in [11, 10]. Note that the convergence of the l-LK method requires $\alpha_k \leq 1/M^2$, whereas the analysis in the present paper allows the relaxation parameters $\alpha_k$ to be much larger than $1/M^2$.

The l-SDK method consists in incorporating the Kaczmarz strategy (with the loping parameters $\omega_k$) in the steepest descent method. This strategy is analog to the one introduced in [11] regarding the Landweber-Kaczmarz iteration. As usual in Kaczmarz-type algorithms, a group of $N$ subsequent steps (starting at some multiple $k$ of $N$) shall be called a cycle. The iteration should be terminated when, for the first time, all $x_k$ are equal within a cycle. That is, we stop the iteration at

$$k_d^* := \arg \min \{ lN \in \mathbb{N} : x_{lN} = x_{lN+1} = \cdots = x_{lN+N-1} \}, \quad (8)$$

Notice that $k_d^*$ is the smallest multiple of $N$ such that

$$x_{k_d^*} = x_{k_d^*+1} = \cdots = x_{k_d^*+N-1}. \quad (9)$$

In the case of noise free data, $\delta^i = 0$ in (1), we choose $\omega_k \equiv 1$ and the iteration (4) - (7) reduces to the Steepest-Descent-Kaczmarz (SDK) method, which is closely related to the Landweber-Kaczmarz (LK) method considered in [17].

It is worth noticing that, for noisy data, the l-SDK method is fundamentally different from the SDK method: The bang-bang relaxation parameter $\omega_k$ effects that the iterates defined in (4) become stationary if all components of the residual vector $\|F_i(x_k^δ) - y^δ_i\|$ fall below a pre-specified threshold. This
characteristic renders (4) – (7) a regularization method (see Section 3). Another consequence of using these relaxation parameters is the fact that, after a large number of iterations, \( \omega_k \) will vanish for some \( k \) within each iteration cycle. Therefore, the computational expensive evaluation of \( F'_k(x_k)^* \) might be loped, making the LSDK method in (4) - (7) a fast alternative to the LK method in [17]. Since in praxis the steepest descent method performs better than the Landweber method, the L-SDK is expected to be more efficient than the L-LK method [10, 11]. Our numerical experiments (mainly for the nonlinear problem in Section 5) corroborate this conjecture.

The article is outlined as follows. In Section 2 we formulate basic assumptions and derive some auxiliary estimates required for the analysis. In Section 3 we provide a convergence analysis for the L-SDK method. In Sections 4 and 4 we compare the numerical performance of the L-SDK method with other standard methods for inverse problems in photoacoustic tomography and in semiconductors respectively.

2 Assumptions and Basic Results

We begin this section by introducing some assumptions, that are necessary for the convergence analysis presented in the next section. These assumptions derive from the classical assumptions used in the analysis of iterative regularization methods [7, 16, 29].

First, we assume that the operators \( F_i \) are continuously Fréchet differentiable, and also that there exist \( x_0 \in X \), \( M > 0 \), and \( \rho > 0 \) such that

\[
\|F'_i(x)\| \leq M, \quad x \in B_\rho(x_0) \subset \bigcap_{i=0}^{N-1} D_i.
\] (10)

Notice that \( x_0^\delta = x_0 \) is used as starting value of the L-SDK iteration. Next we make an uniform assumption on the nonlinearity of the operators \( F_i \). Namely, we assume that the local tangential cone condition [7, 16]

\[
\|F_i(x) - F_i(\bar{x}) - F'_i(\bar{x})(x - \bar{x})\|_Y \
\leq \eta\|F_i(x) - F_i(\bar{x})\|_Y, \quad x, \bar{x} \in B_\rho(x_0)
\] (11)

holds for some \( \eta < 1/2 \). Moreover, we assume the existence of an element \( x^* \in B_{\rho/2}(x_0) \) such that \( F(x^*) = y \).

where \( y = (y^0, \ldots, y^{N-1}) \) is the exact data satisfying (1).

We are now in position to choose the positive constants \( \alpha_{min}, \tau \) in (7), (6). For the rest of this article we shall assume

\[
\alpha_{min} \geq \Phi_{rel} \left(1/M^2\right),
\] (13)

\[
\tau \geq 2 \frac{1 + \eta}{1 - 2\eta} \geq 2.
\] (14)
In particular, for linear problems we can choose $\tau$ equal to 2.

In the sequel we verify some basic results that are necessary for the convergence analysis derived in the next section. The first result concerns the well-definedness and positivity of the relaxation parameter $\alpha_k$.

**Lemma 2.1.** Let assumptions (10)-(12) be satisfied. Then the coefficients $\alpha_k$ in (7) are well-defined and positive.

**Proof.** If $\omega_k = 0$, the assertion follows from (7). If $\omega_k = 1$, then $\|F[k](x_k^\delta) - y_k^\delta\| \geq \tau \delta[k]$ and the assertion is a consequence of [29, Lemma 3.1], applied to $F[k]$ instead of $F$. □

In the next lemma we prove an estimate for the step size of the l-SDK iteration.

**Lemma 2.2.** Let $s_k$ and $\alpha_k$ be defined by (5) and (7). Then

$$\alpha_k \|s_k\|^2 \leq \|F[k](x_k^\delta) - y_k^\delta\|^2, \quad k \in \mathbb{N}.$$  \hspace{1cm} (15)

**Proof.** It is enough to consider the case $\omega_k = 1$. It follows from (7) that

$$\alpha_k \|s_k\|^2 = \Phi_{\text{rel}} \left( \frac{\|s_k\|^2}{\|F'[k](x_k^\delta)s_k\|^2} \right) \|s_k\|^2 \leq \frac{\|s_k\|^4}{\|F'[k](x_k^\delta)s_k\|^2}. \hspace{1cm} (16)$$

Moreover, from the definition of $s_k$ we obtain

$$\|F'[k](x_k^\delta)s_k\| = \|F'[k](x_k^\delta)F'[k](x_k^\delta)^*[F[k](x_k^\delta) - y_k^\delta]\|,$$

$$\|s_k\|^2 \leq \|F'[k](x_k^\delta)F'[k](x_k^\delta)^*[F[k](x_k^\delta) - y_k^\delta]\| \|F[k](x_k^\delta) - y_k^\delta\|.$$

Now, substituting the last two expressions in (16), shows (15). □

The following Lemma is an important auxiliary result, which will be used at several places throughout the article.

**Lemma 2.3.** Let $x_k^\delta$, $\alpha_k$, $\omega_k$, and $s_k$ be defined by (4) - (7) and assume that (11), (12) hold true. If $x_k^\delta \in B_{\rho/2}(x^\ast)$ for some $k \geq 0$, then

$$\|x_{k+1}^\delta - x^\ast\|^2 - \|x_k^\delta - x^\ast\|^2 \leq \omega_k \alpha_k \|F[k](x_k^\delta) - y_k^\delta\| \left( (2\eta - 1)\|F[k](x_k^\delta) - y_k^\delta\| + 2(1 + \eta)\delta[k] \right). \hspace{1cm} (17)$$
Proof. If \( \omega_k = 0 \), then \( x_{k+1} = x_k \) and (17) follows with equality. If \( \omega_k \neq 0 \), it follows from (4) and (5) and Lemma 2.2 that
\[
\|x^\delta_{k+1} - x^*\|^2 - \|x^\delta_k - x^*\|^2
= 2\langle x^\delta_k - x^*, x^\delta_{k+1} - x^\delta_k \rangle + \|x^\delta_{k+1} - x^\delta_k\|^2
= 2\omega_k\alpha_k \langle x^\delta_k - x^*, F'[(x^\delta_k)](y^\delta_k) - F_k(x^\delta_k) \rangle + (\alpha_k\omega_k)^2\|s_k\|^2
\leq 2\omega_k\alpha_k \langle y^\delta_k - F_k(x^\delta_k), F'[(x^\delta_k)](x^\delta_k - x^*) \rangle + \omega_k\alpha_k \|F_k(x^\delta_k) - y^\delta_k\|^2
\leq \omega_k\alpha_k \left( 2\|y^\delta_k - F_k(x^\delta_k), F'[(x^\delta_k)](x^* - x^\delta_k) - F_k(x^*) + F_k(x^\delta_k) \right)
+ 2\langle y^\delta_k - F_k(x^\delta_k), y^\delta_k - y^\delta_k \rangle - \|y^\delta_k - F_k(x^\delta_k)\|^2 \right).
\]
Now, applying (11) with \( x = x^* \) and \( \bar{x} = x^\delta_k \in B_{\rho/2}(x^*) \subset B_{\rho}(x_0) \), leads to
\[
\|x^\delta_{k+1} - x^*\|^2 - \|x^\delta_k - x^*\|^2
\leq \omega_k\alpha_k \|F_k(x^\delta_k) - y^\delta_k\|^2 \left( 2\eta\|F_k(x^\delta_k) - y^\delta_k\| + 2\delta_k - \|F_k(x^\delta_k) - y^\delta_k\| \right).
\]
The last inequality and (1) show (17).

Our next goal is to prove a monotony property, known to be satisfied by other iterative regularization methods, e.g., by the Landweber [7], the steepest descent [29], the LK [17], and the L-LK [11] method.

Proposition 2.4 (Monotonicity). Under the assumptions of Lemma 2.3,
\[
\|x^\delta_{k+1} - x^*\|^2 \leq \|x^\delta_k - x^*\|^2, \quad k \in \mathbb{N}.
\]
Moreover, all iterates \( x^\delta_k \) remain in \( B_{\rho/2}(x^*) \subset B_{\rho}(x_0) \) and satisfy (17).

Proof. From (12) it follows that \( x_0 \in B_{\rho/2}(x^*) \). If \( \omega^\delta_0 = 0 \), then \( x_1 \) satisfies (18) with equality and \( x_1 \in B_{\rho/2}(x^*) \subset B_{\rho}(x_0) \). If \( \omega^\delta_0 \neq 0 \), then Lemma 2.3 implies
\[
\|x^\delta_{1} - x^*\|^2 - \|x^\delta_0 - x^*\|^2 \geq (2\eta - 1)\|F_0(x^\delta_0) - y^\delta_0\| + 2(1 + \eta)\delta^0
\geq \delta^0 \left( (2\eta - 1)\tau + 2(1 + \eta) \right) \geq 0.
\]
Therefore (18), for \( k = 0 \), follows from (14). In particular, \( x_1 \in B_{\rho/2}(x^*) \). An inductive argument implies (18) and that \( x_k \in B_{\rho/2}(x^*) \subset B_{\rho}(x_0) \) for all \( k \in \mathbb{N} \). The assertions therefore follows from Lemma 2.3.

3 Convergence Analysis of the Loping Steepest Descent Kaczmarz Method

In this section we provide a complete convergence analysis for the L-SDK iteration, showing that it is a convergent regularization method in the sense
of [7] (see Theorems 3.3 and 3.6 below). Throughout this section, we assume that (10) - (12) hold, and that \( x_k^\delta \), \( \alpha_k \), \( \omega_k \), and \( s_k \) are defined by (4) - (7).

Our first goal is to prove convergence of the l-SDK iteration for \( \delta = 0 \). For exact data \( y = (y_0, \ldots, y_{N-1}) \), the iterates in (4) are denoted by \( x_k \).

**Lemma 3.1.** There exists a \( x_0 \)-minimal norm solution \( x^\dagger \) of (2) in \( B_{\rho/2}(x_0) \), i.e., a solution \( x^\dagger \) of (2) such that

\[
\| x^\dagger - x_0 \| = \inf \{ \| x - x_0 \| : x \in B_{\rho/2}(x_0) \text{ and } F(x) = y \}.
\]

Moreover, \( x^\dagger \) is the only solution of (2) in \( B_{\rho/2}(x_0) \) \( \cap \) \( (x_0 + \ker(F'(x^\dagger)))^\perp \).

**Proof.** Lemma 3.1 is a consequence of [13, Proposition 2.1]. A detailed proof can be found in [16]. □

**Lemma 3.2.** For all \( k \in \mathbb{N} \), we have \( \alpha_k \geq \underline{\alpha} \).

**Proof.** For the \( \omega_k = 0 \) the claimed estimate holds with equality. If \( \omega_k = 1 \), it follows from (10) that

\[
\frac{\| s_k \|^2}{\| F'_{[k]}(x_k^\delta) s_k \|^2} \geq \frac{\| F'_{[k]}(x_k^\delta) \|^2}{\| F'_{[k]}(x_k^\delta) \|^2} \geq 1/M^2.
\]

Now the monotonicity of \( \Phi_{\text{rel}} \) implies \( \alpha_k \geq \Phi_{\text{rel}}(M^{-2}) = \alpha_{\text{min}} \). □

Throughout the rest of this article, \( x^\dagger \) denotes the \( x_0 \)-minimal norm solution of (2). We define \( e_k := x^\dagger - x_k \). From Proposition 2.4 it follows that (17) holds for all \( k \). By adding over all \( k \), this leads to

\[
\sum_{i=0}^\infty \alpha_i \| y_{[i]} - F_{[i]}(x_i) \|^2 \leq \frac{\| x_0 - x^\dagger \|}{1 - 2\eta} < \infty. \quad (19)
\]

Equation (19) and the monotony of \( \| e_k \| \) shown in Proposition 2.4 are main ingredients in the following proof of the convergence of the SDK iteration.

**Theorem 3.3** (Convergence for Exact Data). For exact data, the iteration \( (x_k) \) converges to a solution of (2), as \( k \to \infty \). Moreover, if

\[
\mathcal{N}(F'(x^\dagger)) \subseteq \mathcal{N}(F(x)) \text{ for all } x \in B_{\rho}(x_0), \quad (20)
\]

then \( x_k \to x^\dagger \).

**Proof.** From (18) it follows that \( \| e_k \| \) decreases monotonically and therefore that \( \| e_k \| \) converges to some \( a \geq 0 \). In the following we show that \( e_k \) is in fact a Cauchy sequence.

\[1\text{This is a standard notation used in the literature.} \]
For \( k = k_0N + k_1 \) and \( l = l_0N + l_1 \) with \( k \leq l \) and \( k_1, l_1 \in \{0, \ldots, N - 1\} \), let \( n_0 \in \{k_0, \ldots, l_0\} \) be such that
\[
\sum_{i_1=0}^{N-1} \| F_{i_1}(x_{Nn_0+i_1}) - y_{i_1} \| \leq \sum_{n_1=0}^{N-1} \| F_{i_1}(x_{Nn_0+i_1}) - y_{i_1} \|, \quad i_0 \in \{k_0, \ldots, l_0\}.
\]
(21)

Then, with \( n := Nn_0 + N - 1 \), we have
\[
\| e_k - e_l \| \leq \| e_k - e_n \| + \| e_l - e_n \|
\]
(22)
and
\[
\| e_n - e_k \|^2 = \| e_k \|^2 - \| e_n \|^2 + 2\langle e_n - e_k, e_n \rangle^2.
\]
\[
\| e_n - e_l \|^2 = \| e_l \|^2 - \| e_n \|^2 + 2\langle e_n - e_l, e_n \rangle^2.
\]
(23)
For \( k \to \infty \), the first two terms of (23) converge to \( \epsilon - \epsilon = 0 \). Therefore, in order to show that \( e_k \) is a Cauchy sequence, it is sufficient to prove that \( \langle e_n - e_k, e_n \rangle \) and \( \langle e_n - e_l, e_n \rangle \) converge to zero as \( k \to \infty \).

To that end, we write \( i = Nn_0 + i_1, i_1 \in \{0, \ldots, N - 1\} \) and set \( i^* := Nn_0 + i_1 \). Then, using the definition of the steepest descent Kaczmarz iteration it follows that
\[
\langle e_n - e_k, e_n \rangle
\]
\[
\quad = \sum_{i=k}^{n-1} \alpha_i \langle F'_{i_1}(x_{i^*})(y^{i_1} - F_{i_1}(x_{i_1})), x^\top - x_n \rangle
\]
\[
\quad \leq \sum_{i=k}^{n-1} \alpha_i \left| \langle y^{i_1} - F_{i_1}(x_{i_1}), F'_{i_1}(x_{i_1})(x^\top - x_{i^*}) + F'_{i_1}(x_{i_1})(x_{i^*} - x_n) \rangle \right|
\]
\[
\quad \leq \sum_{i=k}^{l-1} \alpha_i \| y^{i_1} - F_{i_1}(x_{i_1}) \| \| F'_{i_1}(x_{i_1})(x^\top - x_{i^*}) \| + \sum_{i=k}^{l-1} \alpha_i \| y^{i_1} - F_{i_1}(x_{i_1}) \| \| F'_{i_1}(x_{i_1})(x_{i^*} - x_n) \|.
\]
(24)

From (11) it follows immediately that
\[
\| F'_{i_1}(x_{i_1})(x^\top - x_{i^*}) \| \leq (1 + \eta) \| y^{i_1} - F_{i_1}(x_{i^*}) \|.
\]
(25)
Again using the definition of the steepest descent Kaczmarz iteration and equations (7), (10), it follows that
\[
\| F'_{i_1}(x_{i_1})(x_{i^*} - x_n) \| \leq M \| x_{i^*} - x_n \|
\]
\[
\quad \leq M \sum_{j=i_1}^{N-2} \alpha_j \| F_j(x_{Nn_0+j})^\top (F_j(x_{Nn_0+j}) - y_j) \|
\]
\[
\quad \leq \alpha_{\max} M^2 \sum_{j=i_1}^{N-2} \| F_j(x_{Nn_0+j}) - y_j \| \leq \sum_{j=0}^{N-1} \| F_j(x_{Nn_0+j}) - y_j \|.
\]
(26)
where, for the last estimate we used that \( \alpha_{\text{max}}M^2 = \Phi_{\text{rel}}(\alpha_{\text{max}})M^2 \leq 1 \).
Substituting (25), (26) in (24) leads to
\[
|\langle e_n - e_k, e_n \rangle| \leq (2 + \eta) \sum_{i_0 = k_0}^{n-1} \sum_{i_1 = 0}^{N-1} \alpha_i \| y_i^1 - \Phi_i(x_{N_i0 + i_1}) \| \left( \sum_{j=0}^{N-1} \| F_j(x_{N_i0+j}) - y_j \| \right) \\
\leq (2 + \eta)\alpha_{\text{max}} \sum_{i_0 = k_0}^{n-1} \left( \sum_{i_1 = 0}^{N-1} \| y_i^1 - \Phi_i(x_{N_i0 + i_1}) \| \right)^2.
\]
Because of (19), the last sum tends to infinity for \( k = Nk_0 + k_1 \to \infty \), and therefore \( \langle e_n, e_n - e_k \rangle \to 0 \). Analogously one shows that \( \langle e_n, e_n - e_l \rangle \to 0 \).
Therefore \( e_k \) is a Cauchy sequence and \( x_k = x^1 - e_k \) converges to an element \( x^* \in X \). Because all residuals \( \| F_i(x_k) - y_i \| \) tend to zero, \( x^* \) is solution of (2).

Now assume \( \mathcal{N}(F'(x^1)) \subseteq \mathcal{N}(F(x)) \), for \( x \in B_\rho(x_0) \). Then from the definition of \( x_k \) it follows that
\[
x_{k+1} - x_k \in \mathcal{R}(F'(x_k)) \subseteq \mathcal{N}(F'(x_k))^\perp \subset \mathcal{N}(F'(x^1))^\perp.
\]
An inductive argument shows that all iterates \( x_k \) are elements of \( x_0 + \mathcal{N}(F'(x^1))^\perp \). Together with the continuity of \( F'(x^1) \) this implies that \( x^* \in x_0 + \mathcal{N}(F'(x^1))^\perp \). By Lemma 3.1, \( x^1 \) is the only solution of (2) in \( B_{\rho/2}(x_0) \cap (x_0 + \mathcal{N}(F'(x^1))^\perp) \), and so the second assertion follows.

The second goal in this section is to prove that \( x_k^\delta \) converges to a solution of (2), as \( \delta \to 0 \). First we verify that, for noisy data, the stopping index \( k^\delta \) defined in (8) is finite.

**Proposition 3.4 (Stopping Index).** Assume \( \delta_{\text{min}} := \min\{\delta_0, \ldots, \delta_{N-1}\} > 0 \).
Then \( k^\delta \) defined in (8) is finite, and
\[
\| F_i(x_k^\delta) - y_i \| \leq \tau \delta^i, \quad i = 0, \ldots, N - 1.
\]

**Proof.** Assume that for every \( l \in N \), there exists \( i(l) \in \{0, \ldots, N - 1\} \) such that \( x_{lN+i(l)} \neq x_{lN} \). From Proposition 2.4 follows that we can apply (17) recursively for \( k = 1, \ldots, lN \) and obtain
\[
-\| x_0 - x^* \|^2 \leq \sum_{k=1}^{lN} \omega_k \alpha_k \delta_{[k]} \| F_{[k]}(x_k^\delta) - y_{[k]}^\delta \| \\
\leq \left( 2(1 + \eta)\delta_{[k]} - (1 - 2\eta)\| F_{[k]}(x_k^\delta) - y_{[k]}^\delta \| \right), \quad l \in N.
\]
Using the fact that, either \( \omega_k = 0 \) or \( \| F_{[k]}(x_k^\delta) - y_{[k]}^\delta \| > \tau \delta^k \), implies
\[
\| x_0 - x^* \|^2 \geq \left( \tau (1 - 2\eta) - 2(1 + \eta) \right) \sum_{k=1}^{\infty} \alpha_k \delta_{[k]} \| F_{[k]}(x_k^\delta) - y_{[k]}^\delta \|. \tag{28}
\]
Equation (28) and Lemma 3.2 imply
\[
\| x_0 - x^* \|^2 > \left( \tau (1 - 2\eta) - 2(1 + \eta) \right) \alpha \delta_{\text{min}} l, \quad l \in \mathbb{N}. \tag{29}
\]
The right hand side in (29) tends to infinity, which gives a contradiction. Consequently, \( \{ l \in \mathbb{N} : x_{l+N+i} = x_{lN+i}, 0 \leq i \leq N - 1 \} \neq \emptyset \) and the infimum in (8) takes a finite value.

To prove (27), assume to the contrary, that \( \| F_i(x_k^\delta) - y_i^\delta \| > \tau \delta^i \) for some \( i \in \{0, \ldots, N-1\} \). From (6) and (8) it follows that, \( \omega_k = 1 \) and \( x_{k_i+i}^\delta = x_{k_i+i+1}^\delta \) respectively. Thus, Proposition 2.4 and Lemma 2.1 imply
\[
0 \leq (2\eta - 1)\| F_i(x_k^\delta) - y_i^\delta \| + 2(1 + \eta)\delta^i < \delta^i \left( (2\eta - 1)\tau + 2(1 + \eta) \right).
\]
This contradicts (14), concluding the proof of (27).

The last auxiliary result concerns the continuity of \( x_k^\delta \) at \( \delta = 0 \). For \( y, y^\delta \in Y^N, \delta > 0 \), and \( k \in \mathbb{N} \) we define
\[
\Delta_k(\delta, y, y^\delta) := \omega_k F_{[k]}(x_k^\delta)^* (F_{[k]}(x_k^\delta) - y_{[k]}^\delta) - F_{[k]}(x_k)^* (F_{[k]}(x_k) - y_{[k]}).
\]

**Lemma 3.5.** For all \( k \in \mathbb{N} \),
\[
\lim_{\delta \to 0} \sup \{ \| \Delta_k(\delta, y, y^\delta) \| : y^\delta \in Y^N, \| y_i - y_i^\delta \| \leq \delta_i \} = 0. \tag{30}
\]
Moreover, \( x_{k+1}^\delta \to x_{k+1} \), as \( \delta \to 0 \).

**Proof.** We prove Lemma 3.5 by induction. The case \( k = 0 \) is similar to the case general case and is omitted.

Now, assume \( k > 0 \) and that (30) holds for all \( k' < k \). First we note that (30) and the continuity of \( F_{\text{rel}} \) obviously imply \( x_{k+1}^\delta \to x_{k+1} \), as \( \delta \to 0 \) because. For the proof of (30) we consider two cases. In the first case, \( \omega_k = 1 \), we have
\[
\| \Delta_k(\delta, y, y^\delta) \| = \| F_{[k]}(x_k^\delta)^* (F_{[k]}(x_k^\delta) - y_{[k]}^\delta) - F_{[k]}(x_k)^* (F_{[k]}(x_k) - y_{[k]}) \|
\]
In the second case \( \omega_k = 0 \) we have \( \| F_{[k]}(x_k^\delta) - y_{[k]}^\delta \| \leq \tau \delta^k \) and consequently
\[
\| \Delta_k(\delta, y, y^\delta) \| \leq \| F_{[k]}(x_k^\delta)^* (F_{[k]}(x_k) - y_{[k]}) \|
\]
\[
\leq \| F_{[k]}(x_k^\delta) \| \left( \| F_{[k]}(x_k) - F_{[k]}(x_k^\delta) \| + \| F_{[k]}(x_k^\delta) - y_{[k]} \| + \| y_{[k]} - y_{[k]}^\delta \| \right)
\]
\[
\leq \| F_{[k]}(x_k^\delta) \| \left( \| F_{[k]}(x_k) - F_{[k]}(x_k^\delta) \| + (\tau + 1) \delta_{[k]} \right).
\]
Now (30) follows from (10), the continuity of \( F_{[k]} \) and \( F_{[k]}^* \), and the induction hypothesis (which implies \( x_k^\delta \to x_k \)).
Theorem 3.6 (Convergence for Noisy Data). Assume \((\delta_j^0, \ldots, \delta_j^{N-1})\) is a sequence in \((0, \infty)^N\) with \(\lim_{j \to \infty} \delta_j^i = 0\), for \(j \in \mathbb{N}\). Let \((y_j^0, \ldots, y_j^{N-1})\) be a sequence of noisy data satisfying
\[
\|y_i^j - y_i\| \leq \delta_j^i, \quad i = 0, \ldots, N - 1, j \in \mathbb{N},
\]
and let \(k^j := k^j(\delta_j^j, y_j^{\delta_j^j})\) denote the corresponding stopping index defined in (8). Then \(x_{j, k^j}\) converges to a solution of (2), as \(j \to \infty\). Moreover, if (20) holds, then \(x_{j, k^j} \to x^\dagger\).

Proof. Let \(x^*\) denote the limit of the iterates \(x_k\) which is a solution of (2), cf. Theorem 3.3. From Lemma 3.5 and the continuity of \(F_i\) we know that, for any fixed \(k \in \mathbb{N}\),
\[
x_{j, k}^{\delta_j^j} \to x_k, \quad F_i(x_{j, k}^{\delta_j^j}) \to F_i(x_k), \quad \text{as } j \to \infty. \tag{31}
\]
To show that \(x_{j, k}^{\delta_j^j} \to x^*\), we first assume that \(k^j\) has a finite accumulation point \(k^*\). Without loss of generality we may assume that \(k^j = k^*\) for all \(j \in \mathbb{N}\). From Proposition 3.4 we now that \(\|y_i^{\delta_j^j} - F_i(x_{j, k^j}^{\delta_j^j})\| < \tau \delta_j^j\) and, by taking the limit \(j \to \infty\), that \(y_i^j = F_i(x_{k^*}^j)\). Consequently \(x_{k^*}^j = x^*\) and \(x_{j, k}^{\delta_j^j} \to x^*\) as \(j \to \infty\).

It remains to consider the case where \(k^j \to \infty\) as \(j \to \infty\). To that end let \(\varepsilon > 0\). Without loss of generality we assume that \(k^j\) is monotonically increasing. According to Theorem 3.3 we can choose \(n \in \mathbb{N}\) such that \(\|x_{k^*}^n - x^*\| < \varepsilon/2\). Equation (31) implies that there exists \(j_0 > n\) such that \(\|x_{j_0}^{\delta_j^j} - x_{k^*}^n\| < \varepsilon/2\) and Proposition 2.4 imply
\[
\|x_{j, k}^{\delta_j^j} - x^*\| \leq \|x_{j_0}^{\delta_j^j} - x^*\| \\
\leq \|x_{j_0}^{\delta_j^j} - x_{k^*}^n\| + \|x_{k^*}^n - x^*\| < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon, \quad \text{for } j \geq j_0.
\]
Consequently, \(x_{j, k}^{\delta_j^j} \to x^*\).

If (20) holds true, then by Theorem 3.3 \(x^* = x^\dagger\). Therefore \(x_{j, k}^{\delta_j^j} \to x^\dagger\), which concludes the proof. \(\square\)

Remark 3.7. In standard iterative regularization methods the number of performed iterations plays the role of the regularization parameter [7, 16]. A parameter choice rule corresponds to the choice of an appropriate stopping index \(k^j = k(\delta, y^j)\).

For the loping Kaczmarz iterations analyzed in this article, the situation is quite different. If \(k\) is fixed, then the iterates \(x_k^j\), do not depend continuously on data \(y_k^j\). However, for a fixed sequence \((\omega_k)\) of loping parameters, the iterates \(x_k^j\) do depend continuously on \(y_k^j\): Now, the loping sequences \((\omega_k)\) play the role of the regularization parameters and the particular sequence \(\omega_k = \omega_k(\delta, y^j)\), depending on \(\delta\) and the noisy data \(y^j\), is the a-posteriori parameter choice rule.
Figure 2: The left picture shows the phantom $x^\dagger$, where the white dots indicate the locations of the detectors. The corresponding data $(y_i^\delta)_i$ are depicted on the right.

4 Limited View Problem in Photoacoustic Computed Tomography

In this section we compare the numerical performance of loping Kaczmarz methods applied to a system of linear equations related to a limited view problem in photoacoustic computed tomography [8, 18, 28, 34].

Let $X := L^2(D)$ denote the Hilbert space of all square integrable functions in the unit disc $D \subset \mathbb{R}^2$, and let $Y$ denote the Hilbert space of all functions $y : [0, 2] \to \mathbb{R}$ with $\|y\| := \int_0^2 y(t) t dt < \infty$. We consider the system

$$M_i x = y_i, \quad i = 0, \ldots, N - 1,$$

(32)

where $M_i : X \to Y$,

$$(M_i x)(t) := \frac{1}{\sqrt{\pi}} \int_{S^1} x(\xi_i + t\sigma) d\Omega(\sigma), \quad t \in [0, 2],$$

(33)

are scaled versions of circular mean Radon transform. Solving (32) is the crucial step in three-dimensional photoacoustic computed tomography with integrating linear detectors [9, 28], where the centers of integration, $\xi_i$, correspond to the positions of the linear detectors. The operators $M_i$ are linear, bounded, and satisfy $\|M_i\| \leq 1$, [10]. For linear bounded operators, the tangential cone condition (11) is satisfied with $\eta = 0$. Consequently, the L-SDK method (4) - (7) provides a convergent regularization method for solving (32). The adjoint of $M_i$, required in (5) is given by $(M_i^* y)(\xi) = y(|\xi_i - \xi|)/\sqrt{\pi}$, [10].

In the following numerical examples, we consider the L-SDK method with either the choice $\Phi_{\text{rel}}(s) = \alpha_{\text{min}} s$ (which minimizes $\|F[y](x_{k+1}^\delta) - y_{k+1}^\delta\|^2$) or $\Phi_{\text{rel}}(s) = \alpha_{\text{min}}$ (which corresponds to the L-LLK method). In both cases
we use $\alpha_{\text{min}} = 0.4$ or $\alpha_{\text{min}} = 1$. We will assume $N = 50$ measurements, where the centers $\xi_i = R(\sin(\pi i/(N - 1))\cos(\pi i/(N - 1)))$ are uniformly distributed on the semicircle $S^+ := \{\xi_1, \xi_2) \in \partial B_R : \xi_1 \geq 0\}$. Micro-local analysis predicts, that in such a limited angle situation where the centers do not cover the hole circle, certain details (the invisible boundaries) of $x$ outside the detection region (convex hull of $S^+$) cannot be recovered [21, 27, 35]. The phantom $x^\dagger_1$, shown in the left picture in Figure 2, consists of a superposition of characteristic functions and one Gaussian kernel. Data $y_i = M_i x^\dagger_1$ was calculated via numerical integration with the trapezoidal rule and 4% noise was added, such that $\|y_i - y_i^\delta\|/\|y_i\| \approx 0.04$.

Figures 3 and 4 show the reconstruction error $e_k^\delta := \|x_k^\delta - x^\dagger\|$ and the number of actually performed iterations respectively. For comparison purposes, the error for the SDK and the LK iteration (without loping parameter) are plotted. The smaller relaxation parameter $\omega_{\text{min}}$ gives smaller reconstruction errors. This behavior is typically for the application of Kaczmarz type iterations to Radon transforms [5, 24]; therefore in praxis often
relatively small relaxation parameters are chosen. As can be seen in Figure 3, for the larger relaxation parameter, the loping strategy significantly reduces the reconstruction error. For the smaller relaxation parameter, the regularized solution of the loping Kaczmarz methods have errors comparable to the optimal solution of their non-loping counterparts when stopped after the cycle with minimal error (which is not available in practice). In Figure 5 the regularized solutions are depicted with $\alpha_{\min} = 0.4$.

Table 1: Numerical performance of Kaczmarz methods for $\hat{\alpha} = 0.4$, and the CGNE method. The non-loping iterations are stopped after the cycle when the error $\|x_k^\alpha - x^\dagger\|$ is minimal.

To point out the effectiveness of the loping Kaczmarz methods for solving linear inconsistent systems we included the reconstruction error for the CGNE iteration (conjugate gradient [14, 31] applied to normal equations). If stooped appropriately the CGNE method is known to be a regularization method [7, 12]. As can be seen in Figure 3 the error for the L-SDK and the L-LK methods much smaller that for the CGNE iteration. In Table 1 run times on a 2 GHz Intel Core Duo iMac are compared. The image is reconstructed on a $120 \times 120$ grid.
5 An inverse doping problem

In this section we present another comparison of the numerical performance of the L-SDK, L-LK and LK methods. This time we consider an application related to inverse doping problems for semiconductors [2, 10, 20, 3] For details on the mathematical modeling of this inverse problem we refer the reader to [10, Section 3].

In what follows we describe the abstract formulation in Hilbert spaces of the problem (the so called inverse doping problem in the linearized unipolar model for current flow measurements). Let \( \Omega = (0, 1) \times (0, 1) \subset \mathbb{R}^2 \) be the domain representing the semiconductor device (a diode). The two semiconductor contacts are represented by the boundary parts:

\[
\Gamma_0 := \{(s, 0) : s \in (0, 1)\}, \quad \Gamma_1 := \{(s, 1) : s \in (0, 1)\},
\]

(we denote \( \partial \Omega_D := \Gamma_0 \cup \Gamma_1 \)) while the insulated surfaces of the semiconductor are represented by \( \partial \Omega_N := \{(0, t) : t \in (0, 1)\} \cup \{(1, t) : t \in (0, 1)\} \).

This specific inverse doping problem can be reduced to the identification of the positive parameter function \( x \) (the doping profile \( C \) is related to \( x \) by \( C = x - \lambda^2 \Delta (\ln x) \)) in the model

\[
\begin{align*}
\mu_n \nabla \cdot (x(\xi) \nabla u) &= 0, & \text{in } \Omega \\
u &= U(\xi), & \text{on } \partial \Omega_D \\
abla u \cdot \nu &= 0, & \text{on } \partial \Omega_N
\end{align*}
\]

from measurements of the Voltage–Current map (the forward operator)

\[
\Sigma_x : H^{3/2}(\partial \Omega_D) \to \mathbb{R}, \quad U \mapsto \mu_n \int_{\Gamma_1} e^{V_{bi}(\xi)} u_{\nu}(\xi) \, d\Gamma
\]

which maps an applied potential \( U \) at \( \partial \Omega_D \) to the corresponding total current flow \( \Sigma_x(U) \) through the contact \( \Gamma_1 \). Here \( \mu_n, \lambda \) are positive constants and \( V_{bi} \) is a known logarithmic function defined on \( \partial \Omega_D \).

Due to the nature of the practical experiments that can be performed on a factory environment, some restrictions on the data have to be taken into account:

1. The voltage profiles \( U \in H^{3/2}(\partial \Omega_D) \) must satisfy \( U(\xi) \equiv 0 \) at the contact \( \Gamma_1 \).

2. The parameter \( x \) has to be determined from a finite number of measurements, i.e. from the data

\[
y^\delta_i := \Sigma_x(U_i) \in Y := \mathbb{R}, \quad i = 0, \ldots, N - 1,
\]

where the \( U_i \in H^{3/2}(\partial \Omega_D) \) are prescribed voltage profiles satisfying 1.
Figure 6: In the top left picture, the doping profile to be identified. In the top right picture, a typical voltage profile $U_i$ and the corresponding solution $u$ of $(34)–(36)$. The initial guess used for the 1-SDK, 1-LK and LK iterative methods is shown in the bottom picture. The boundary parts $\Gamma_0$ and $\Gamma_1$ correspond to the top right and to the lower left edge respectively (the origin is the right corner).

Therefore we can model the inverse doping problem with a system of operator equations of the form (2), namely

$$F_i(x) = y_i^\delta, \quad i = 0, \ldots, N - 1,$$

where $x \in L^2(\Omega) =: X$ is the unknown parameter, $y_i^\delta \in \mathbb{R} =: Y$ denote the measured data, $F_i : X \to Y$ defined by $F_i(x) := \Sigma_x(U_i)$ are the parameter to output maps, with domains of definition

$$D_i := \{x \in L^\infty(\Omega) : 0 < x_{\text{min}} \leq x \leq x_{\text{max}}, \text{ a.e.}\}.$$ 

It is worth mentioning that, although the operators $F_i$ are Fréchet differentiable, they do not satisfy the tangential cone condition (11). Therefore, the convergence results derived in Section 3 cannot be applied.

In the following numerical examples we assume that $N = 11$ Dirichlet–Neumann pairs $(U_i, F_i(x'))$ of measurement data are available. The fixed inputs $U_i$, are chosen to be piecewise constant functions supported in $\Gamma_0$

$$U_i(s) := \begin{cases} 1, & |s - s_i| \leq h \\ 0, & \text{else} \end{cases}$$
where the points $s_i$ are uniformly distributed on $\Gamma_0$ and $h = 1/32$. The doping profile to be reconstructed is shown in Figure 6 (top left picture). The top right picture of Figure 6 shows a typical voltage profile $U_j$ (applied at $\Gamma_0$) as well as the corresponding solution $u$ of (34)–(36). In these pictures, as well as in the forthcoming ones, $\Gamma_1$ appears on the lower left edge and $\Gamma_0$ on the top right edge (the origin corresponds to the upper right corner).

In Figure 7 we show the evolution of the iteration error for the l-SDK, l-LK and LK methods. The same initial guess was used for the three methods (see Figure 6). In our computations we chose $\tau = 2.5$ in (14). The
Computed iterative steps within each cycle

Figure 8: Comparison between the performance of $l$-SDK and $l$-LK methods.

The solid (blue) line shows the actually performed number of steps within each cycle of the $l$-SDK method, while the dashed (red) line gives the corresponding information with respect to the $l$-LK method.

In order to obtain the same accuracy with the LK method, 380 cycles are required.

In the top pictures of Figure 7 one can see the iteration error for the $l$-SDK method after 10 and 81 cycles. For comparison purposes, the iteration error for the $l$-LK method is shown after 80 and 121 cycles (see the central pictures of Figure 7). The bottom pictures of Figure 7 show the iteration error for the LK method after 120 and 380 cycles. The number of actually computed iterative steps within each cycle of the $l$-SDK and $l$-LK methods is shown in Figure 8.

We provide a complete convergence analysis for the $l$-SDK iteration, proving that it is a convergent regularization method in the sense of [7]. Moreover, we prove a convergence result for the SDK iteration. From Theorem 3.3 follows that the SDK is a convergent method for exact data.

What concerns the numerical experiments for the inverse doping problem, the $l$-LK method requires almost 50% more cycles than the $l$-SDK method in order to reach the stop criteria (8). Moreover, the LK method requires almost three times more cycles than the $l$-LK method in order to achieve the same accuracy (see [10] for other comparisons between the LK and $l$-LK methods). The efficiency of the $l$-SDK method becomes even more evident when we compare the total number of actually performed iterative steps. Each cycle of the LK method requires the computation of 11 steps, while in the $l$-SDK and $l$-LK methods the number of actually performed steps per cycle is very small after a few number of cycles. As
one can see in Figure 8, no more than 2 steepest descent steps per cycle are computed after the 14-th cycle of the \( l \)-SDK method. Analogously, no more than 2 Landweber steps per cycle are computed after the 37-th cycle of the \( l \)-LK method. In total, for the computation of the LK-approximation in Figure 7 (380 cycles), 4180 Landweber steps are needed, while the \( l \)-LK-approximation (121 cycles) requires the computation of 258 Landweber steps and the \( l \)-SDK-approximation (81 cycles) requires the computation of 184 steepest descent steps.

6 Conclusions

In this paper we propose a new iterative method for inverse problems of the form (2), namely the \( l \)-SDK method. As a by-product we also formulated the SDK iteration, which is the steepest descent counterpart of the LK method [17].

In the \( l \)-SDK iteration we omit an update of the SDK iteration (within one cycle) if corresponding \( i \)-th residual is below some threshold. Consequently, the \( l \)-SDK method is not stopped until all residuals are below the specified threshold. The \( l \)-SDK method is the steepest descent counterpart of the \( l \)-LK iteration [11, 10].
