Evolution by Non-Convex Functionals

P. Elbau, M. Grasmair F. Lenzen, O. Scherzer

RICAM-Report 2008-29
Abstract

We establish a semi-group solution concept for morphological differential equations, such as the mean curvature flow equation. The proposed method consists in generating flows from generalized minimizers of non-convex energy functionals. We use relaxation and convexification to define generalized minimizers. The main part of this work consists in verification of the solution concept by comparing analytical, rotationally invariant solutions of the mean curvature flow equation and iterative minimizer of a non-convex energy functional.

1 Introduction

Semi-group theory is a powerful concept for proving existence of solutions of gradient flow equations

$$\begin{align*}
\partial_t u & \in -\partial R(u), \\
u(0) & = u_0,
\end{align*}$$

where $R: X \to [0, +\infty]$ is a sequentially lower semi-continuous, convex energy functional on a Hilbert Space $X$. In (1) we use the notation that $\partial$ with a subscript denotes the derivative of a function with respect to the subscript and without subscript $\partial$ denotes a subdifferential.

Standard results on gradient flows state that equation (1) has a solution $u$ whenever $u_0 \in D(R)$, and that $u(t), t > 0$, can be computed as limit of the sequence $u_{t/n}$ defined by

$$u_{t/n}^{(n)} := (\text{Id} + \frac{t}{n} \partial R)^{-n} u_0$$

as $n \to \infty$ (cf. [3, 5, 6, 14, 16]). Equivalently, one can consider the iteration

$$u_{t/n}^{(0)} := u_0 \quad \text{and} \quad u_{t/n}^{(k)} := \text{arg min}_{u \in U} \left\{ \frac{1}{2} \| u - u_{t/n}^{(k-1)} \|^2 + \frac{t}{n} R(u) : u \in U \right\}, \quad k = 1, \ldots, n. \quad (2)$$
Then, again, the equality $u(t) = \lim_{n \to \infty} u^{(n)}_{t/n}$ holds.

In [2], this idea has been extended to gradient flows on metric spaces $(X, d)$ by considering the iterative minimization of the functional

$$\mathcal{F}(\tau, \bar{u}; u) := d(u, \bar{u})^2 + \tau R(u)$$

instead. Again, the limit of the iteration solves a gradient flow equation.

Let us now consider a more general form for both the energy functional and the distance measure. For $\tau > 0$ and $\bar{u} \in X$ let $F(\tau, \bar{u}; u)$ be a family of functionals defined by

$$F(\tau, \bar{u}; u) := S(\bar{u}; u) + \tau R(u),$$

where $S : X \times X \to [0, +\infty]$ and $R : X \to [0, +\infty]$ are (not necessarily convex) functionals on $X$. Since we waive the convexity of $S$ and $R$, we are no longer able to characterize minimizers of $F$ based on the subgradients of $S(u)$ and $R(u)$. Moreover, using direct methods (see [11, 7]), we can only assume existence of generalized minimizers. Nevertheless we can apply the semi-group concept and define an iterative method analogously to (2): We define the sequence $\{u^{(n)}_{\tau} \}$ for $n \in \mathbb{N}_0$ by $u^{(0)}_{\tau} := u_0$ and

$$u^{(k)}_{\tau} \in \{ u \in X : u \text{ is a generalized minimizer of } F(\tau, u^{(k-1)}_{\tau}; \cdot) \}. \quad (3)$$

Here, the generalized minimizers are defined via the relaxation of $F$. Again, the sequence $\{u^{(n)}_{\tau}\}$ at least formally defines a flow on $X$.

In Section 3 we apply this concept to a particular functional for which the associated formal gradient flow equation resembles the mean curvature flow equation (see [10]). In the remaining parts of the paper we show that this relation is not just formal. We provide a rigorous proof that for rotationally symmetric, continuous, and initial data with monotonous rotational part the mean curvature flow is in fact generated by this non-convex functional. This example suggests that our non-convex semi-group concept is a reasonable solution concept for geometrical PDEs.

### 2 Evolution by Non-convex Functionals

Let $X$ be a topological space, and let $\mathcal{R} : X \to [0, +\infty]$ and $\mathcal{S} : X \times X \to [0, +\infty]$. Assume that for every $u_0 \in X$ there exists $u \in X$ such that $\mathcal{S}(u_0; u) + \mathcal{R}(u) \neq +\infty$. For $\tau > 0$ and $u_0 \in X$ we define the functional $F(u_0, \tau; \cdot) : X \to [0, +\infty]$ setting

$$F(\tau, u_0; u) := \mathcal{S}(u_0; u) + \tau \mathcal{R}(u).$$

We want to define a flow as limit for $n \to \infty$ of the sequence $\{u^{(n)}_{\tau}\}$ defined by the iteration $u^{(0)}_{\tau} := u_0$ and

$$u^{(k)}_{\tau} = \arg \min \{ F(t/n, u^{(k-1)}_{\tau}; u) : u \in U \}, \quad k = 1, \ldots, n.$$

Since a minimizer need not exist for arbitrary non-convex functionals $\mathcal{R}$ and $\mathcal{S}$, it is necessary to work with generalized minimizers instead, which are defined as minimizers of relaxed functionals.
For the following definition of relaxation recall that a functional $\mathcal{F}$ on the topological space $X$ is called \textit{sequentially coercive}, if all of its sublevel sets are sequentially precompact. Moreover, it is called \textit{proper}, if there exists some $u \in X$ with $\mathcal{F}(u) < \infty$. Finally, the functional $\mathcal{F}$ is \textit{sequentially lower semi-continuous} if
\[
\liminf_{k} \mathcal{F}(u^{(k)}) \geq \mathcal{F}(u) \ \text{whenever} \ u^{(k)} \to u.
\]

**Definition 1.** Let $\mathcal{F}: X \to [0, +\infty]$ be sequentially coercive and proper on the topological space $X$. Assume moreover that $\mathcal{F}$ is bounded from below. We define the \textit{relaxation} of $\mathcal{F}$ as
\[
\mathcal{F}_R := \sup \left\{ J: X \to [0, +\infty] : J \leq \mathcal{F} \text{ is sequentially lower semi-continuous} \right\}.
\]

The following facts easily follow from the definition of $\mathcal{F}_R$:
- Since $\mathcal{F}$ is bounded from below, there exists a constant functional $J_0 = c$ below $\mathcal{F}$. Since the constant functional is sequentially lower semi-continuous, $\mathcal{F}_R$ is well defined.
- The functional $\mathcal{F}_R: X \to [0, +\infty]$ is sequentially lower semi-continuous (cf. \cite{12, Lemma 1.5}). Since the functional $\mathcal{F}_R$ is sequentially coercive and proper, it therefore attains a minimum (cf. \cite{12, Lemma 1.4}).

Moreover, every minimizer of the relaxed functional $\mathcal{F}_R$ can be considered a generalized minimizer of the original functional $\mathcal{F}$.

**Proposition 2.** Every minimizer $u$ of $\mathcal{F}_R$ is a generalized minimizer of $\mathcal{F}$. That is, either $u$ is a minimizer of $\mathcal{F}$ or there exists a sequence $(u^{(k)})$ converging to $u$ such that $\mathcal{F}(u^{(k)}) \to \inf_{v \in X} \mathcal{F}(v)$.

More generally, we have the characterization of the relaxed functional
\[
\mathcal{F}_R(u) = \min \left\{ \liminf_{k} \mathcal{F}(u^{(k)}) : u^{(k)} \to u \right\}
\]
for every $u \in X$.

**Proof.** Cf. \cite{4, Prop. 1.31].

We are now ready to introduce our concept of semi-groups generated by non-convex energy functionals and similarity terms.

**Definition 3.** Let $\mathcal{R}: X \to [0, +\infty]$ and $\mathcal{S}: X \times X \to [0, +\infty]$. For $\tau > 0$ and $\tilde{u} \in X$ define the functional $\mathcal{F}(\tau, \tilde{u}; \cdot): X \to [0, +\infty]$ by
\[
\mathcal{F}(\tau, \tilde{u}; u) := \mathcal{S}(\tilde{u}; u) + \tau \mathcal{R}(u).
\]
Assume that $\mathcal{F}(\tau, \tilde{u}; \cdot)$ is sequentially coercive for every $\tau > 0$ and $\tilde{u} \in X$.

For every $\tau > 0$ we define the piecewise constant approximation $\bar{u}_\tau: \mathbb{R}_{\geq 0} \to X$ by $\bar{u}_\tau(0) = u_0$ and
\[
\bar{u}_\tau(t) \in \arg \min \mathcal{F}_R \left( \tau, u((k - 1)\tau); \cdot \right), \quad (k - 1)\tau < t \leq k\tau, \ k \in \mathbb{N}.
\]

We define the flow generated by $\mathcal{F}$ by
\[
U(t) := \left\{ u(t) : \text{there exist } \tau_t \to 0 \text{ with } u(t) = \lim_{\ell \to \infty} \bar{u}_{\tau_t}(t) \right\}.
\]
We note that for some time $t$ the set $U(t)$ can be empty, in which case no solution of the evolution process exists at the time $t$.

3 MCM and Semi-Group Theory - Analytical Justification

The main motivation for the considerations above is the *mean curvature flow* equation

$$\partial_t u = |\nabla u| \nabla \cdot \left( \frac{\nabla u}{|\nabla u|} \right) \quad \text{on } \mathbb{R}^m \times (0, \infty),$$

and its relation to the evolution defined by a non-convex similarity term and the total variation as energy functional.

This NCBV functional (*non-convex bounded variation*) on $X := L^1(\mathbb{R}^m)$ is defined for $u \in W^{1,1}(\mathbb{R}^m)$ as

$$F(\tau, \tilde{u}; u) := \int_{\mathbb{R}^m} \left( \frac{(u - \tilde{u})^2}{2|\nabla u|} + \tau |\nabla u| \right) dx$$

and $F(\tau, \tilde{u}; u) = +\infty$ for $u \notin W^{1,1}(\mathbb{R}^m)$. Since in general, minimization of $F$ with respect to the last variable $u$ is considered, we will omit the dependence on $\tau$ and $\tilde{u}$ whenever possible and write $F(u) := F(\tau, \tilde{u}; u)$ instead.

The following computations, which are purely formal and by no means mathematically rigorous, provide the link between iterative minimization of $F$ and the mean curvature flow.

Formally, the gradient of the functional $F$ is

$$\partial F(u) = \frac{u - \tilde{u}}{|\nabla u|} + \nabla \cdot \left( \frac{(u - \tilde{u})^2}{2|\nabla u|^2} - \tau \frac{\nabla u}{|\nabla u|} \right).$$

Therefore, a minimizer $u$ of $F$ is expected to satisfy the optimality condition

$$\frac{u - \tilde{u}}{\tau} \in |\nabla u| \nabla \cdot \left( \frac{(u - \tilde{u})^2}{2\tau|\nabla u|^2} \frac{\nabla u}{|\nabla u|} \right).$$

Now denote $\Delta_\tau u := (u - \tilde{u})/\tau$. Then (7) reads as

$$\Delta_\tau u \in |\nabla u| \nabla \cdot \left( \frac{1 - \frac{(u - \tilde{u})^2}{2\tau|\nabla u|^2}}{|\nabla u|} \right).$$

Interpreting $\Delta_\tau u$ as finite difference approximation of $\partial_t u$, a formal passage to the limit $\tau \to 0$ yields the mean curvature flow equation.

We will now show that the flow generated by the functional (6) in fact approximates the solution of the mean curvature equation, if the initial data $u_0$ is absolutely continuous, compactly supported, rotationally invariant, and its radial part is strictly monotonous on its support.

In order to prove this result, we start with the solution of the mean curvature equation (5) for rotationally invariant initial data $u_0 \in C^1(\mathbb{R}^m)$. In this case there exists a function $v_0 \in C^1(\mathbb{R}_{\geq 0})$ such that

$$u_0(x) = v_0(|x|) \quad \text{for every } x \in \mathbb{R}^m.$$
In this setting, the solution $u$ of the mean curvature equation is rotationally invariant. Therefore, there also exists a function $v: \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ such that
\[ u(x,t) = v(|x|,t), \quad (x,t) \in \mathbb{R}^m \times \mathbb{R} \geq 0. \tag{10} \]
Thus, the mean curvature equation reduces to the linear partial differential equation
\[ \partial_t v(r,t) = \frac{m-1}{r} \partial_r v(r,t), \quad v(r,0) = v_0(r). \tag{11} \]
Since the solution of this initial value problem is constant along the characteristic curves $t \mapsto (r(t),t)$ defined by $\partial_t r = -(m-1)/r$, we obtain the solution
\[ v(r,t) = v_0(\sqrt{r^2 + 2(m-1)t}), \quad (r,t) \in \mathbb{R} \geq 0 \times \mathbb{R} \geq 0. \]

We now calculate a solution of the flow generated by the NCBV functional. First, we will determine the relaxation $F_R$ of the functional $F$ in $BV(\mathbb{R}^m)$, the space of functions $u \in L^1(\mathbb{R}^m)$ of bounded variation.

Recall to that end that the distributional gradient $Du$ of a function $u \in BV(\mathbb{R}^m)$ can be decomposed into
\[ Du = \nabla u \mathcal{L}^m + D^s u, \]
where $D^s u$ denotes the singular part of the signed measure $Du$. For further details see e.g. [1, 8].

In the following, we denote by $L^\infty_c(\mathbb{R}^m)$ the space of essentially bounded functions $\tilde u \in L^\infty(\mathbb{R}^m)$ with compact support, and by $BV_c(\mathbb{R}^m)$ the space of all compactly supported functions $\tilde u \in BV(\mathbb{R}^m)$.

**Theorem 4.** Let $\tilde u \in L^\infty(\mathbb{R}^m)$ and $\tau > 0$. Then the relaxation $F_R$ of the functional $F$ with respect to the $L^1$-norm on $BV(\mathbb{R}^m)$ coincides with its convexification $F_c$ defined by
\[ F_c(u) := \begin{cases} \int_{\mathbb{R}^m} f(|u-\tilde u|,|\nabla u|;\tau)dx + \tau |D^s u|(\mathbb{R}^m), & \text{if } u \in BV(\mathbb{R}^m), \\ +\infty, & \text{if } u \notin BV(\mathbb{R}^m), \end{cases} \tag{12} \]
with
\[ f(\xi,\eta;\tau) = \begin{cases} \frac{\xi^2}{2\eta} + \tau\eta, & \text{if } \sqrt{2\tau}\eta > \xi, \\ \sqrt{2\tau}\xi, & \text{if } \sqrt{2\tau}\eta \leq \xi. \end{cases} \tag{13} \]
Moreover, the functional $F$ has a generalized minimizer $u_\tau \in BV(\mathbb{R}^m) \cap L^\infty(\mathbb{R}^m)$ and
\[ \text{ess inf } \tilde u \leq u_\tau \leq \text{ess sup } \tilde u. \]
In addition, $\text{supp}(u_\tau)$ is contained in the closed convex hull of $\text{supp}(\tilde u)$ and $|Du_\tau|(\mathbb{R}^m) \leq |D\tilde u|(\mathbb{R}^m)$.

**Proof.** See Section 4.

**Corollary 5.** Let $u_0 \in BV(\mathbb{R}^m) \cap L^\infty(\mathbb{R}^m)$ and $\tau > 0$. The the flow generated by the NCBV-functional is well-defined.
Theorem 7. Let $v_0: \mathbb{R}_{>0} \rightarrow \mathbb{R}$ be an absolutely continuous function with $\text{supp}(v_0) = [0, R]$ for some $R > 0$, which is strictly monotonous on $[0, R]$. For $k \in \mathbb{N}$ let $v_{\tau}^{(0)} := v_0$ and

$$v_{\tau}^{(k)} \in \arg\min\{\mathcal{G}(\tau, v_{\tau}^{(k-1)}; \cdot) : v \in \mathcal{B}V_c\}.$$
Then
\[ \lim_{n \to \infty} v^{(n)}_t(r) = v_0(\sqrt{r^2 + 2(m-1)t}) \]
locally uniformly for \((r, t) \in \mathbb{R}_{>0} \times \mathbb{R}_{>0}\).

Moreover, we have for all \(k \in \mathbb{N}\) and \(\tau \in \mathbb{R}_{>0}\) the inequality
\[ |v^{(k)}_r(r) - v^{(k-1)}_r(r)| < \sqrt{2\tau |\partial_r v^{(k)}_r(r)|} \]
for almost every \(r \in (0, R)\). (15)

**Proof.** See Section 8. \(\square\)

In particular, the property (15) of Theorem 7 shows that every rotationally invariant minimizer of \(F_R\) fulfills the condition (14) of Proposition 6. Therefore, all minimizers of \(F_R\) are rotationally invariant and Theorem 7 completely describes the flow generated by the NCBV functional \(F\).

**Corollary 8.** The mean curvature flow is equivalent to the flow generated by the NCBV functional in case the initial data is rotationally invariant, absolutely continuous, and its radial component is strictly monotonous on its support.

### 4 Proof of Theorem 4

In this section we prove Theorem 4 which states that the relaxation of the NCBV functional coincides with its convexification and that minimization of \(F_R\) does neither increase the norm nor the support of the input data \(u_0\). This generalizes the results of \([12, 13]\), where the relaxation has been computed on \(BV(\Omega)\) for open and bounded subsets \(\Omega\) of \(\mathbb{R}^m\) with Lipschitz boundary.

**Proof (of Thm. 4).** For proving that the relaxed and convexified functional coincide, i.e., that the equality \(F_R = F_c\) holds, we have to show that \(F_c\) is lower semi-continuous and that for every \(u \in BV(\mathbb{R}^m)\) and \(\varepsilon > 0\) there exists a function \(v_\varepsilon\) with \(\|u_\varepsilon - u\|_2 < \varepsilon\) and \(F(v_\varepsilon) \leq F_c(u) + \varepsilon\). To that end it is convenient to define for every open and bounded set \(\Omega \subset \mathbb{R}^m\) and \(u \in L^1(\mathbb{R}^m)\) the localized functionals
\[
F(u; \Omega) := \int_\Omega \frac{(u - \tilde{u})^2}{2|\nabla u|} + \tau |\nabla u| \, dx,
\]
\[
F_c(u; \Omega) := \int_\Omega f(|u - \tilde{u}|, |\nabla u|; \tau) \, dx + \tau |D^s u|(\Omega).
\]
Here \(|D^s u|(\Omega)| denotes the singular part of the Radon measure \(|Du|\) on \(\Omega\).

Using \([13\text{ Thm. 2}]\), we obtain that \(F_c(\cdot, \Omega)\) is sequentially lower semi-continuous whenever \(\Omega \subset \mathbb{R}^m\) is open and bounded with Lipschitz boundary. Since \(F_c(\cdot) = F_c(\cdot, \mathbb{R}^m)\) is the supremum of all these functionals, it follows that also \(F_c\) is sequentially lower semi-continuous.

Let \(r > 1\) such that \(\text{supp}(\tilde{u}) \subset B_r\). Assume that \(u \in BV(\mathbb{R}^m)\) and that \(\text{supp}(u) \subset B_r\). Using \([13\text{ Thm. 2}]\), it follows that for every \(\varepsilon > 0\) there exists a function \(v_\varepsilon \in W^{1,1}(B_{r+1})\) such that
\[
\|v_\varepsilon - u\|_{L^1(B_{r+1})} \leq \varepsilon \text{ and } F(v_\varepsilon, B_{r+1}) \leq F_c(u, B_{r+1}) + \varepsilon.
\]
(16)

A closer inspection of the proof of \([13\text{ Thm. 2}]\) reveals that \(v_\varepsilon\) can be chosen to be an element of \(W^{1,\infty}(B_{r+1})\).
Let $R$ be a minimizer of the function $s \mapsto \int_{\partial B_s} |v_\varepsilon| \, d\mathcal{H}^{m-1}$ in $[r, r+1]$ and let
\[ C > \max\{\|v_\varepsilon\|_\infty, \|\nabla v_\varepsilon\|_\infty\}. \tag{17} \]
Define
\[ \hat{u}_\varepsilon(x) := \begin{cases} v_\varepsilon(x) & \text{if } |x| \leq R, \\ \varepsilon R \frac{R_x}{|x|} - C (|x| - R) \text{sgn}(v_\varepsilon(R_x/|x|)) & \text{if } v_\varepsilon(R_x/|x|) \geq C(|x| - R) \\ 0 & \text{and } |x| \geq R, \end{cases} \tag{18} \]
and $\Omega_\varepsilon := B_R \cup \text{supp}(\hat{u}_\varepsilon)$. Then
\[ C \leq |\nabla \hat{u}_\varepsilon| \leq 2C \text{ on } \Omega_\varepsilon \setminus B_R. \tag{19} \]
Using the inequality $(R + r)^m \leq 2^m R^{m-1} r + R^m$ for $r \in [0, R]$ and \eqref{17}, we obtain
\[ L^m(\Omega_\varepsilon \setminus B_R) = \int_{S^{m-1}} \int_R^{R + |v_\varepsilon(R_x)|/C} t^{m-1} \, dt \, d\mathcal{H}^{m-1}(x) \]
\[ = \frac{1}{m} \int_{S^{m-1}} \left( \left( R + \frac{|v_\varepsilon(R_x)|}{C} \right)^m - R^m \right) \, d\mathcal{H}^{m-1}(x) \]
\[ \leq \frac{2^m}{C^m} \int_{S^{m-1}} |v_\varepsilon(R_x)| R^{m-1} \, d\mathcal{H}^{m-1}(x) \]
\[ \leq \frac{2^m}{C^m} \int_{\partial B_R} |v_\varepsilon(x)| \, d\mathcal{H}^{m-1}(x). \]
As a consequence, the minimality of $\int_{\partial B_R} |v_\varepsilon| \, d\mathcal{H}^{m-1}$ implies that
\[ L^m(\Omega_\varepsilon \setminus B_R) \leq \frac{2^m}{C^m} \int_{\partial B_R} |v_\varepsilon(x)| \, d\mathcal{H}^{m-1}(x) \]
\[ \leq \frac{2^m}{C^m} \int_r^{r+1} \int_{\partial B_t} |v_\varepsilon(x)| \, d\mathcal{H}^{m-1}(x) \, dt \]
\[ = \frac{2^m}{C^m} \|v_\varepsilon\|_{L^1(B_{r+1} \setminus B_r)} \]
\[ \leq \frac{2^m}{C^m} \varepsilon. \]
Using \eqref{17} and \eqref{19} and that supp$(\hat{u}) \subset B_r \subset B_R$, we obtain that
\[ \mathcal{F}(\hat{u}_\varepsilon; \Omega_\varepsilon \setminus B_R) = \int_{\Omega_\varepsilon \setminus B_R} \frac{\hat{u}_\varepsilon^2}{2|\nabla \hat{u}_\varepsilon|} + \tau |\nabla \hat{u}_\varepsilon| \, dx \]
\[ \leq (2\tau C + C/2) L^m(\Omega_\varepsilon \setminus B_R) \]
\[ \leq \varepsilon (2\tau + 1/2) \frac{2^m}{C^m}. \]
Since $\hat{u}_\varepsilon$ is absolutely continuous, it follows with \eqref{18} that
\[ \mathcal{F}(\hat{u}_\varepsilon; \Omega_\varepsilon) \leq \mathcal{F}(\hat{u}_\varepsilon; B_R) + \mathcal{F}(\hat{u}_\varepsilon; \Omega \setminus B_R) \]
\[ \leq \mathcal{F}(v_\varepsilon; B_R) + K \varepsilon \leq \mathcal{F}_c(u; \Omega_\varepsilon) + (K + 1)\varepsilon, \]
where \( K := (2\tau + 1/2)2m \).

Taking into account the definition [13] of \( \hat{u}_\varepsilon \), we obtain that
\[
\| \hat{u}_\varepsilon - u \|_{L^1(\Omega_\varepsilon)} = \| v_\varepsilon - u \|_{L^1(B_R)} + \| \hat{u}_\varepsilon \|_{L^1(B_{r+1}\setminus B_R)} \\
\leq \varepsilon + \int_R^{r+1} |\hat{u}_\varepsilon| \, dt \, dH^{m-1} \\
\leq \varepsilon + \int_R^{r+1} |v_\varepsilon| \, dt \, dH^{m-1} \\
= \varepsilon + \|v_\varepsilon\|_{L^1(B_{r+1}\setminus B_r)} \leq 2\varepsilon.
\]

Now let \( U_k \subset \mathbb{R}^m \setminus \Omega_\varepsilon, k \in \mathbb{N} \), be disjoint, open, bounded, and Lipschitz bounded sets such that \( \mathcal{L}^m(\mathbb{R}^m \setminus (\Omega_\varepsilon \cup \bigcup_k U_k)) = 0 \). Since \( \text{supp}(u) \) and \( \text{supp}(\hat{u}) \) are contained in \( B_r \), which is a subset of \( \Omega_\varepsilon \), it follows that \( \mathcal{F}_c(u; U_k) = 0 \).

Therefore there exists for every \( k \in \mathbb{N} \) a function \( \hat{u}_k \in W^{1,\infty}(\mathbb{R}^m) \) with \( \text{supp}(u_k) \subset \overline{U}_k \) such that \( \|\hat{u}_k\|_{L^1(U_k)} < \varepsilon/2^k \) and \( \mathcal{F}(\hat{u}_k; U_k) < \varepsilon/2^k \). Setting
\[
u_\varepsilon(x) := \begin{cases} \hat{u}_\varepsilon(x) & \text{if } x \in \Omega_\varepsilon, \\ \hat{u}_k(x) & \text{if } x \in U_k, \; k \in \mathbb{N}, \end{cases}
\]
it follows that \( \|\nu_\varepsilon - u\|_{L^1(\mathbb{R}^m)} < 3\varepsilon \) and \( \mathcal{F}(\nu_\varepsilon) \leq \mathcal{F}(u) + (K + 2)\varepsilon \). Since \( \varepsilon > 0 \) was arbitrary and \( K \) independent of \( \varepsilon \), this shows that \( \mathcal{F}_c(u) \geq \mathcal{F}_R(u) \) whenever \( u \in L^1(\mathbb{R}^m) \) is compactly supported.

Now let \( u \in L^1(\mathbb{R}^m) \) be arbitrary. Then \( \mathcal{F}_c(u) = \lim_{k \to \infty} \mathcal{F}_c(u \chi_{B_k}) \), where \( \chi_{B_k} \) denotes the characteristic function of \( B_k \). Consequently,
\[
\mathcal{F}_R(u) \leq \liminf_{k \to \infty} \mathcal{F}_R(u \chi_{B_k}) \leq \liminf_{k \to \infty} \mathcal{F}_c(u \chi_{B_k}) = \mathcal{F}_c(u),
\]
which shows that \( \mathcal{F}_R(u) = \mathcal{F}_c(u) \) for every \( u \in L^1(\mathbb{R}^m) \).

Now let \( u \in BV(\mathbb{R}^m) \). Denote by \( B \) the closed convex hull of \( \text{supp}(\hat{u}) \) and define \( u_B := u \chi_B \). Then
\[
|Du|(\mathbb{R}^m \setminus B \cup \partial B) \geq \int_{\partial B} |u| \, dH^{m-1} = |Du_B|(\mathbb{R}^m \setminus B \cup \partial B).
\]
As a consequence, \( \mathcal{F}_c(u_B) \leq \mathcal{F}_c(u) \) with equality holding if and only if \( u_B = u \). Similarly, defining \( \hat{u}(x) := \max\{\min\{u(x), \text{sup } \hat{u}\}, \text{inf } \hat{u}\} \), one can show that \( \mathcal{F}_c(\hat{u}) \leq \mathcal{F}_c(u) \), and again, equality holds if and only if \( \hat{u} = u \) (cf. [12, Lemma 4.12]). This shows that minimizing \( \mathcal{F}_c \) on \( L^1(\mathbb{R}^m) \) is equivalent to minimizing \( \mathcal{F}_c \) on the compact set
\[
S := \{ u \in L^1(\mathbb{R}^m) : \inf \hat{u} \leq u \leq \sup \hat{u}, \; \text{supp}(u) \subset B \}.
\]
Since \( \mathcal{F}_c \) is lower semi-continuous, the existence of a minimizer \( u_\tau \), which is contained in \( S \), follows.

From [12] and [13] it follows that
\[
\tau|Du_\tau|(\mathbb{R}^m) \leq \mathcal{F}_c(u_\tau) \leq \mathcal{F}_c(\hat{u}) = \tau|D\hat{u}|(\mathbb{R}^m).
\]
\[\square\]
5 Proof of Proposition 6

Proposition 6 states that, given an SO($m$)-invariant function $\tilde{u}$, the functional $\mathcal{F}_\mathcal{R}(\tau, \tilde{u}; \cdot)$ has an SO($m$)-invariant minimizer. In addition, it provides a criterion to determine whether every minimizer is SO($m$)-invariant.

**Proof (of Proposition 6).** Theorem 4 implies the existence of a minimizer $u_\tau \in BV_c(\mathbb{R}^m)$ of $\mathcal{F}_\mathcal{R}(\tau, \tilde{u}; \cdot)$. We then define the SO($m$)-invariant function $\bar{u}_\tau \in BV_c(\mathbb{R}^m)$ by

$$
\bar{u}_\tau(x) = \int_{O(m)} u_\tau(Rx) d\mu(R),
$$

where $\mu$ denotes the Haar-measure on the orthogonal group $O(m)$ of all real, orthogonal $m \times m$-matrices, normalized to fulfill $\mu(O(m)) = 1$.

For the distributional gradient $D\bar{u}_\tau$ of $\bar{u}_\tau$, we find with $\psi_R(y) := R\phi(R^{-1}y)$

$$
\int_{\mathbb{R}^m} \phi(x) \cdot dD\bar{u}_\tau(x) = -\int_{\mathbb{R}^m} \bar{u}_\tau(x) \nabla \cdot \phi(x) dx = \int_{O(m)} \int_{\mathbb{R}^m} u_\tau(Rx) \nabla \cdot \phi(x) dx d\mu(R) = \int_{O(m)} \int_{\mathbb{R}^m} u_\tau(y) \nabla \cdot \psi_R(y) dy d\mu(R)
$$

for every function $\phi \in C_0^\infty(\mathbb{R}^m; \mathbb{R}^m)$. Therefore, using the definition of the distributional gradient of $u_\tau$, we get

$$
\int_{\mathbb{R}^m} \phi(x) \cdot dD\bar{u}_\tau(x) = \int_{O(m)} \int_{\mathbb{R}^m} R\phi(R^{-1}y) \cdot dD\bar{u}_\tau(y) d\mu(R)
$$

$$
= \int_{O(m)} \int_{\mathbb{R}^m} \phi(x) \cdot R^{-1}dD\bar{u}_\tau(Rx) d\mu(R).
$$

For the measure $|D\bar{u}_\tau|$, we thus have for all measurable sets $A \subset \mathbb{R}^m$ the inequality

$$
|D\bar{u}_\tau|(A) \leq \int_{O(m)} |D\bar{u}_\tau|(RA) d\mu(R). \tag{21}
$$

We next define the function

$$
F : BV(\mathbb{R}^m; [0, \infty)) \times \mathcal{M}(\mathbb{R}^m) \times \mathbb{R}_{>0} \to \mathbb{R} \cup \{\infty\},
$$

$$
F(\xi, \sigma; \tau) := \int_{\mathbb{R}^m} f(\xi(x), \sigma^0(x); \tau) dx + \sigma^*(\mathbb{R}^m).
$$

Here, $BV(\mathbb{R}^m; [0, \infty))$ is the set of all functions $\xi : \mathbb{R}^m \to [0, \infty)$ with bounded variation and $\mathcal{M}(\mathbb{R}^m)$ denotes the space of finite Radon measures on $\mathbb{R}^m$. Moreover, $\sigma = \sigma^0 \mathcal{L}(m) + \sigma^*$ is the Lebesgue decomposition of the measure $\sigma$ into its absolutely continuous and its singular part.

Defining the measure $\nu_\tau(A) := \int_{O(m)} |D\bar{u}_\tau|(RA) d\mu(R)$, we get with the inequality (21) and the fact that the function $f$ is monotonically increasing in its second argument that

$$
F(\xi, |D\bar{u}_\tau|; \tau) \leq F(\xi, \nu_\tau; \tau), \tag{22}
$$

10
where the inequality is strict if $|D^s\bar{u}_\tau|(\mathbb{R}^m) < \nu^s(\mathbb{R}^m)$ or
\[
\mathcal{L}^{(m)}(\{x \in \mathbb{R}^m : \sqrt{2\tau} |\nabla \bar{u}_\tau(x)| > \xi(x) \text{ and } |\nabla \bar{u}_\tau(x)| < \nu^s(x)\}) \neq 0. \quad (23)
\]

With the estimate (22) and the monotonicity of $f$ in its first argument, we thus find
\[
\mathcal{F}_\mathcal{R}(\tau, \bar{u}; \bar{u}_\tau) = F(|\bar{u}_\tau - \bar{u}|, |D\bar{u}_\tau|; \tau) \\
\leq F(|\bar{u}_\tau - \bar{u}|, \nu; \tau) \\
\leq F\left(\int_{\Omega(m)} |u_\tau \circ R - \bar{u} \circ R|d\mu(R), \nu; \tau\right). 
\]

Now, since the function $f(\cdot, \cdot; \tau)$ is convex, we see that the functional $F(\cdot, \cdot; \tau)$ is convex as well. We may therefore apply Jensen’s inequality to get
\[
\mathcal{F}_\mathcal{R}(\tau, \bar{u}; \bar{u}_\tau) \leq \int_{\Omega(m)} F(|u_\tau \circ R - \bar{u} \circ R|, |D{u}_\tau| \circ R; \tau)d\mu(R),
\]
and since $F(\xi \circ R, \sigma \circ R; \tau) = F(\xi, \sigma; \tau)$ for every $R \in \Omega(m)$, we finally have
\[
\mathcal{F}_\mathcal{R}(\tau, \bar{u}; \bar{u}_\tau) \leq F(|u_\tau - \bar{u}|, |D{u}_\tau|; \tau) = \mathcal{F}_\mathcal{R}(\tau, \bar{u}; u_\tau).
\]

If we further know that
\[
\mathcal{L}^{m}(\{x \in \mathbb{R}^m : \sqrt{2\tau} |\nabla \bar{u}_\tau(x)| \leq |\bar{u}_\tau(x) - \bar{u}(x)|\}) = 0,
\]
then, according to (23), the inequality (24) is strict if $|D\bar{u}_\tau|(\mathbb{R}^m) < \nu(\mathbb{R}^m)$. It therefore only remains to show that the equality $|D\bar{u}_\tau|(\mathbb{R}^m) = |D{u}_\tau|(\mathbb{R}^m)$ implies that $u_\tau$ is $\text{SO}(m)$-invariant.

So, let $|D\bar{u}_\tau|(\mathbb{R}^m) = |D{u}_\tau|(\mathbb{R}^m)$. In a first step, we will show that the Radon–Nikodým derivative $\frac{d\bar{u}_\tau}{d|D{u}_\tau|}(x)$ is orthogonal to the sphere. Introducing the function
\[
\tilde{\phi}(x) = \int_{\Omega(m)} R\phi(R^{-1}x)d\mu(R),
\]
we see from equation (24) that $|D\bar{u}_\tau|(\mathbb{R}^m)$ can be written as
\[
|D\bar{u}_\tau|(\mathbb{R}^m) = \sup_{\phi \in \mathcal{C}} \int_{\mathbb{R}^m} \tilde{\phi}(x) \cdot d{u}_\tau(x),
\]
where $\mathcal{C}$ denotes the set of all functions $\phi \in C^\infty(\mathbb{R}^m; \mathbb{R}^m)$ with $\|\phi\|_\infty \leq 1$ and $
\tilde{\phi}(Rx) = R\phi(x)$ for every $x \in \mathbb{R}^m$ and every $R \in \Omega(m)$.

The symmetry property $\phi(Rx) = R\phi(x)$ implies that $\tilde{\phi}(x) = \epsilon(x)\phi(x)|x|$, $\epsilon(x) \in \{-1, 1\}$, and therefore
\[
|D\bar{u}_\tau|(\mathbb{R}^m) \leq \int_{\mathbb{R}^m} \frac{|x|}{|x|} \frac{d{u}_\tau}{d|D{u}_\tau|}(x) \ d|D{u}_\tau|(x).
\]

The condition $|D\bar{u}_\tau|(\mathbb{R}^m) = |D{u}_\tau|(\mathbb{R}^m)$ thus demands that
\[
\frac{x}{|x|} \frac{d{u}_\tau}{d|D{u}_\tau|}(x) = 1 \quad \text{for } |D{u}_\tau|\text{-almost every } x \in \mathbb{R}^m, \quad (25)
\]
that is, \( \frac{dDu_\tau}{d|Du_\tau|}(x) \) is orthogonal to the sphere.

Now note that for \(|Du_\tau|\)-almost every \( x \in \mathbb{R}^m \) the vector \( \frac{dDu_\tau}{d|Du_\tau|}(x) \) equals the inner normal to the boundary of the level sets \( \Omega_t := \{ y \in \mathbb{R}^m : u_\tau(y) \geq t \} \), \( u^-_\tau(x) \leq t \leq u^+_\tau(x) \) (cf. [9, Thm. 4.5.9, (17), (25)]). Using the coarea formula, it follows that the same equality holds for \( \mathcal{H}^{m-1} \)-almost every \( x \in \partial \Omega_t \) for almost every \( t \in \mathbb{R} \). Consequently, (25) implies that almost all normals to level sets of \( u_\tau \) point in direction orthogonal to spheres centered at zero. However, this is only possible, if the boundary of each level set of \( u_\tau \) is the union of spheres, in other words, if \( u_\tau \) is constant on each sphere \( \partial B_r \). □

6 Properties of Rotationally Invariant Minimizers

In order to investigate the iterative minimization procedure of Definition 3 for the functional \( G \), we will collect some properties of the minimizers \( v_\tau \in \hat{BV}_c \) of the functional \( G(\tau, \tilde{v}; \cdot) \).

Assumption 9. \( \tilde{v} : \mathbb{R}_{\geq 0} \to \mathbb{R} \) is continuous and satisfies \( \tilde{v} \in \hat{BV}_c \), supp(\( \tilde{v} \)) = [0, R], and it is not locally constant on \((0, R)\), i.e.,

\[
\mathcal{L}^1 \left( \{ r \in (0, R) : \partial_r \tilde{v}(r) = 0 \} \right) = 0.
\]

Before we come to the minimizers, let us first mention a few properties of the function \( f \) found in the integrand of \( G \). For its partial derivatives, we find directly from its definition (13) that

\[
\partial_\xi f(\xi, \eta; \tau) = \begin{cases} \frac{\xi}{\sqrt{2\tau}}, & \text{if } \sqrt{2\tau} \eta > \xi, \\ \eta, & \text{if } \sqrt{2\tau} \eta \leq \xi, \end{cases}
\]

(26)

\[
\partial_\eta f(\xi, \eta; \tau) = \begin{cases} \tau - \frac{\xi^2}{2\eta^2}, & \text{if } \sqrt{2\tau} \eta > \xi, \\ 0, & \text{if } \sqrt{2\tau} \eta \leq \xi. \end{cases}
\]

(27)

Thus, \( f(\cdot; \cdot; \tau) \in C^1(\mathbb{R}_{\geq 0}^2 \setminus \{(0,0)\}) \) and we have

\[
\partial_\eta f(\xi, \eta; \tau) \in [0, \tau] \quad \text{for every } (\xi, \eta) \in \mathbb{R}_{\geq 0}^2 \setminus \{(0,0)\}
\]

(28)

and

\[
\partial_\eta f(\xi, 0; \tau) = 0 \quad \text{for every } \xi > 0.
\]

(29)

In particular, we have the estimates

\[
\|\partial_\xi f(\cdot; \cdot; \tau)\|_\infty \leq \sqrt{2\tau} \quad \text{and} \quad \|\partial_\eta f(\cdot; \cdot; \tau)\|_\infty \leq \tau.
\]

Let now \( v_\tau \in \hat{BV}_c \) be a minimizer of the functional \( G(\tau, \tilde{v}; \cdot) \). We define the sets

\[
\Omega_\tau := \{ r \in (0, R) : |v_\tau(r) - \tilde{v}(r)| < \sqrt{2\tau} |\partial_r v_\tau(r)| \},
\]

(30)

\[
\Sigma_\tau := \{ r \in (0, R) : |v_\tau(r) - \tilde{v}(r)| \geq \sqrt{2\tau} |\partial_r v_\tau(r)| \}. \]
In the sequel we will rewrite the Euler–Lagrange equations for the functional $G(\tau, \tilde{v}; \cdot)$ in terms of the function
g_{\tau} : (0, R) \to \mathbb{R},
g_{\tau}(r) := \begin{cases} \frac{v_{\tau}(r) - \tilde{v}(r)}{\partial_{r} v_{\tau}(r)}, & \text{if } r \in \Omega_{\tau}, \\ \sqrt{2\tau}, & \text{if } r \in \Sigma_{\tau}. \end{cases} \tag{31}

To this end, we remark that we can express the partial derivatives of the integrand of $G$ with the function $g_{\tau}$ only. For $r \in (0, R)$ we namely have the relations
$$
\partial_{\xi} f(|v_{\tau}(r) - \tilde{v}(r)|, |\partial_{r} v_{\tau}(r)|; \tau) = |g_{\tau}(r)|,
\partial_{\eta} f(|v_{\tau}(r) - \tilde{v}(r)|, |\partial_{r} v_{\tau}(r)|; \tau) = \tau - \frac{g_{\tau}^{2}(r)}{2}. \tag{32}
$$

Moreover, from the definition (31), we see that the function $g_{\tau}$ is bounded. Indeed,
g_{\tau}(r) \in (-\sqrt{2\tau}, \sqrt{2\tau}) \text{ for every } r \in (0, R). \tag{33}

**Lemma 10.** The functions $g_{\tau}$ and $v_{\tau}$ satisfy the following conditions:

1. The function $g_{\tau}^{2}$ is locally absolutely continuous on $(0, R]$ and solves the differential equation
$$
r \partial_{r}(g_{\tau}^{2})(r) = 2(m - 1)\tau - 2r g_{\tau}(r) - (m - 1) g_{\tau}^{2}(r) \tag{34}
$$
almost everywhere on $\Omega_{\tau}$.

2. The function $r \mapsto \text{sgn}(\partial_{r} v_{\tau}(r))$ is locally constant on $\Omega_{\tau}$.

3. The function $r \mapsto g_{\tau}(r) \text{sgn}(v_{\tau}(r) - \tilde{v}(r))$ is continuous on $\Omega_{\tau}$.

4. The function $g_{\tau}$ satisfies $g_{\tau}(r) \neq 0$ for every $r \in (0, R)$.

5. The function $g_{\tau}$ is locally absolutely continuous on every subset of $(0, R)$ where it is continuous.

Here, all the properties of the functions are only valid with the right choice of representative. We especially want to stress that therefore Item 4 does not exclude points in $\Omega_{\tau}$ where $v_{\tau} = \tilde{v}$.

**Proof.** Since, by assumption, the function $\tilde{v}$ is not locally constant on its support, we find that
$$
\mathcal{L}^{1}(\{r \in (0, R) : \partial_{r} v_{\tau}(r) = 0 \text{ and } v_{\tau}(r) = \tilde{v}(r)\}) = \mathcal{L}^{1}(\{r \in (0, R) : \partial_{r} \tilde{v}(r) = 0 \text{ and } v_{\tau}(r) = \tilde{v}(r)\}) = 0.
$$

Therefore, the condition that the variational derivative of $G$ in direction of a function $\phi \in C_{0}^{1}(0, R)$ at the minimizer $v_{\tau}$ of $G(\tau, \tilde{v}; \cdot)$ vanishes reads as
$$
0 = \lim_{t \to 0} \frac{G(\tau, \tilde{v}; v_{\tau} + t\phi) - G(\tau, \tilde{v}; v_{\tau})}{t}
= \int_{0}^{R} \partial_{\xi} f(|v_{\tau}(r) - \tilde{v}(r)|, |\partial_{r} v_{\tau}(r)|; \tau) \text{sgn}(v_{\tau}(r) - \tilde{v}(r)) r^{m-1} \phi(r) \, dr
+ \int_{0}^{R} \partial_{\eta} f(|v_{\tau}(r) - \tilde{v}(r)|, |\partial_{r} v_{\tau}(r)|; \tau) \text{sgn}(\partial_{r} v_{\tau}(r)) r^{m-1} \partial_{r} \phi(r) \, dr. \tag{35}
$$
We now choose for $0 < r_0 < R$ the function $\phi = \phi_\varepsilon = \chi_{(0,r_0)} * \rho_\varepsilon$, where $\rho_\varepsilon(r) := e^{-m\rho(r/\varepsilon)}$ and $\rho$ is some mollifier. We refer to \cite{8} for the basic definition of a mollifier and its properties.

Passing to the limit \( \varepsilon \to 0 \), it follows that

\[
\int_0^{r_0} \partial_t f (|v_\tau(r) - \tilde{v}(r)|, |\partial_\tau v_\tau(r)|; \tau) \operatorname{sgn} (v_\tau(r) - \tilde{v}(r)) r^{m-1} \, dr
= \partial_t f (|v_\tau(r_0) - \tilde{v}(r_0)|, |\partial_\tau v_\tau(r_0)|; \tau) \operatorname{sgn} (\partial_\tau v_\tau(r_0)) r_0^{m-1}
\]

for almost every $r_0 \in (0, R)$.

Since the integrand of the left hand side of \( \square \) is the integral of a bounded function, it follows that the function

\[
r \mapsto \partial_t f (|v_\tau(r) - \tilde{v}(r)|, |\partial_\tau v_\tau(r)|; \tau) \operatorname{sgn} (\partial_\tau v_\tau(r)) \tag{37}
\]

is locally absolutely continuous on \((0, R)\).

Because of the properties \cite{28} and \cite{29} of the function $\partial_t f$, the local absolute continuity of the function \( \square \) also implies the local absolute continuity of the function

\[
r \mapsto \partial_t f (|v_\tau(r) - \tilde{v}(r)|, |\partial_\tau v_\tau(r)|; \tau) = \tau - \frac{g_\tau^2(r)}{2}
\]

on \((0, R)\). Thus, \( g_\tau^2 \) is locally absolutely continuous on \((0, R)\), and therefore, in particular, continuous and differentiable almost everywhere on \((0, R)\).

Moreover, since by definition of the set $\Omega_\tau$ the function $\tau - \frac{g_\tau^2}{2}$ does not become zero on $\Omega_\tau$, the continuity of the map \( \square \) implies that the function $r \mapsto \operatorname{sgn} (\partial_\tau v_\tau(r))$ is locally constant on $\Omega_\tau$. Therefore, the function $\Omega_\tau \to (\sqrt{-2\tau}, \sqrt{2\tau})$,

\[
r \mapsto g_\tau(r) \operatorname{sgn} (v_\tau(r) - \tilde{v}(r)) = |g_\tau(r)| \operatorname{sgn} (\partial_\tau v_\tau(r))
\]

is continuous on $\Omega_\tau$.

Differentiating equation \( \square \), we find that

\[
r^{m-1} g_\tau(r) = \partial_r \left( r^{m-1} - \frac{r_\tau^{m-1} g_\tau(r)^2}{2} \right)
\]

for almost every $r \in \Omega_\tau$,

which evaluates to the differential equation \( \square \). This finishes the proof of the first three items.

To prove Item 4, we note that the right hand side of \( \square \) is strictly positive for

\[
g_{\tau,-}(r) := -\frac{r}{m-1} - \frac{r^2}{(m-1)^2 + 2\tau} < g_\tau(r)
< -\frac{r}{m-1} + \frac{r^2}{(m-1)^2 + 2\tau} =: g_{\tau,+}(r) \tag{38}
\]

Consequently, the derivative of the non-negative function $g_\tau^2$ is strictly positive on a neighbourhood of every point $r_0 \in \Omega_\tau$ with $g_\tau(r_0) = 0$, which is impossible.

If therefore $g_\tau$ is continuous on some compact interval $I \subset (0, R)$, then either $g_\tau = \sqrt{g_\tau^2}$ or $g_\tau = -\sqrt{g_\tau^2}$ on $I$. But since the square root is a locally Lipschitz continuous function on $\mathbb{R}_{>0}$, this implies that $g_\tau$ is absolutely continuous on $I$, proving Item 5. \( \square \)
Since the function $g_\tau$ only captures the absolutely continuous part of the distributional derivative $Dv_\tau$, we would still need to deal with the singular part $D^s v_\tau$. But it turns out that the minimizer $v_\tau$ is in fact locally absolutely continuous and so the singular part is zero.

**Lemma 11.** The function $v_\tau$ is locally absolutely continuous, that is, the singular part of $Dv_\tau$ satisfies $|D^s v_\tau|((\mathbb{R}_{>0}) = 0$.

**Proof.** Since $v_\tau$ is a minimizer of the convex functional $G(\tau, \tilde{v}; \cdot)$, the one-sided variational derivative

$$\delta_\phi G(\tau, \tilde{v}; v_\tau) := \lim_{t \to 0^+} \frac{G(\tau, \tilde{v}; v_\tau + t\phi) - G(\tau, \tilde{v}; v_\tau)}{t}$$

exists and is non-negative for all variations $\phi \in \tilde{BV}_c$.

Let us now assume that $|D^s v_\tau|((0, R)) \neq 0$. Then there exists $r_0 \in (0, R)$ such that

$$|D^s v_\tau|([r_0 - \varepsilon, r_0]) \neq 0 \quad \text{for every } \varepsilon \in (0, r_0).$$

We further choose for $\varepsilon \in (0, \min\{r_0, R-r_0\})$ a function $\phi \in \tilde{BV}_c$ with $\phi_{[r_0, \infty)} \in C^1([r_0, \infty))$ and

$$\phi(r) = 0 \quad \text{for } r \in \mathbb{R}_{\geq 0} \setminus (r_0 - \varepsilon, r_0 + \varepsilon),$$

$$\phi(r) = -D^s v_\tau([r_0 - \varepsilon, r]) \quad \text{for } r \in (r_0 - \varepsilon, r_0].$$

Then in particular $\partial_\tau \phi(r) = 0$ for $r \not\in [r_0, r_0 + \varepsilon]$ and

$$D\phi([r_0 - \varepsilon, r]) = D^s \phi([r_0 - \varepsilon, r]) = -D^s v_\tau([r_0 - \varepsilon, r])$$

for $r \in [r_0 - \varepsilon, r_0]$. Thus we find that

$$\delta_\phi G(\tau, \tilde{v}; v_\tau)$$

$$= \int_{r_0 - \varepsilon}^{r_0 + \varepsilon} \partial_\xi f\left(|v_\tau(r) - \tilde{v}(r)|, |\partial_\tau v_\tau(r)|; \tau \right) \text{sgn}(v_\tau(r) - \tilde{v}(r)) r^{m-1} \phi(r) \, dr$$

$$+ \int_{r_0}^{r_0 + \varepsilon} \partial_\eta f\left(|v_\tau(r) - \tilde{v}(r)|, |\partial_\tau v_\tau(r)|; \tau \right) \text{sgn}(\partial_\tau v_\tau(r)) r^{m-1} \partial_\tau \phi(r) \, dr$$

$$- \tau \int_{[r_0 - \varepsilon, r_0]} r^{m-1} \, d|D^s \phi|(r).$$

Now define the function $\psi \in C^1_c([0, R])$ setting $\psi(r) = \phi(r)$ for $r > r_0$ and $\psi(r) = \phi(r_0)$ for $r \leq r_0$. Since $v_\tau$ is a minimizer of $G(\tau, \tilde{v}; \cdot)$, it follows that the Euler–Lagrange equation holds for $\psi$ and therefore

$$\int_{r_0}^{r_0 + \varepsilon} \partial_\eta f\left(|v_\tau(r) - \tilde{v}(r)|, |\partial_\tau v_\tau(r)|; \tau \right) \text{sgn}(\partial_\tau v_\tau(r)) r^{m-1} \partial_\tau \phi(r) \, dr$$

$$= - \int_0^{r_0 + \varepsilon} \partial_\xi f\left(|v_\tau(r) - \tilde{v}(r)|, |\partial_\tau v_\tau(r)|; \tau \right) \text{sgn}(v_\tau(r) - \tilde{v}(r)) r^{m-1} \psi(r) \, dr$$

$$= - \int_{r_0}^{r_0 + \varepsilon} \partial_\xi f\left(|v_\tau(r) - \tilde{v}(r)|, |\partial_\tau v_\tau(r)|; \tau \right) \text{sgn}(v_\tau(r) - \tilde{v}(r)) r^{m-1} \phi(r) \, dr$$

$$- \phi(r_0) \int_0^{r_0} \partial_\xi f\left(|v_\tau(r) - \tilde{v}(r)|, |\partial_\tau v_\tau(r)|; \tau \right) \text{sgn}(v_\tau(r) - \tilde{v}(r)) r^{m-1} \, dr.$$
Therefore (41) and (38) imply that
\[
\delta \phi \mathcal{G}(\tau, \tilde{v}; v_r)
\]
\[
= \int_{r_0 - \varepsilon}^{r_0} \partial \xi f \left( |v_r(r) - \tilde{v}(r)|, |\partial_r v_r(r)|; \tau \right) \text{sgn}(v_r(r) - \tilde{v}(r)) r^{m-1} \phi(r) \, dr
\]
\[
- \partial \eta f \left( |v_r(r_0) - \tilde{v}(r_0)|, |\partial_r v_r(r_0)|; \tau \right) \text{sgn}(\partial_r v_r(r_0)) r_0^{m-1} \phi(r_0)
\]
\[
- \tau \int_{r_0 - \varepsilon}^{r_0} r^{m-1} \, d|D^s \phi|(r) . \quad (41)
\]

From (39) we obtain that
\[
|D^s \phi|(r_0 - \varepsilon, r_0) = |D \phi|(r_0 - \varepsilon, r_0) \geq C := \sup \{|\phi(r)| : r \in [r_0 - \varepsilon, r_0]\} .
\]

Using the relation (32) between \(g_r\) and the partial derivatives of \(f\), the inequality (41) therefore implies that
\[
\delta \phi \mathcal{G}(\tau, \tilde{v}; v_r) \leq \int_{r_0 - \varepsilon}^{r_0} |g_r(r)| |\phi(r)| r^{m-1} \, dr + \left( \tau - \frac{g_r^2(r_0)}{2} \right) r_0^{m-1} |\phi(r_0)|
\]
\[
- C \tau (r_0 - \varepsilon)^{m-1}
\]
\[
\leq C \left( \sqrt{2 \tau} r_0^{m-1} \varepsilon + \tau (r_0^{m-1} - (r_0 - \varepsilon)^{m-1}) - \frac{r_0^{m-1}}{2} g_r^2(r_0) \right),
\]
which becomes negative for sufficiently small \(\varepsilon\). Thus the function \(v_r\) is absolutely continuous on the interval \((0, R)\).

Theorem 4 implies that \(v_r(r) = 0\) for \(r > R\). It therefore only remains to show that \(v_r\) is continuous at the point \(R\). So assume that \(\lim_{r \to R^-} v_r(r) = \Delta \neq 0\). Using the continuity of \(\tilde{v}\), we would then find some \(\varepsilon > 0\) such that \((v_r(r) - \tilde{v}(r)) \text{sgn}(\Delta) > 0\) for all \(r \in (R - \varepsilon, R)\). The variational derivative in the direction of \(\phi = -\text{sgn}(\Delta) \chi_{(R-\varepsilon, R)} \in BV_c\) would then be
\[
\delta \phi \mathcal{G}(\tau, \tilde{v}; v_r) = -\int_{R-\varepsilon}^{R} \partial \xi f \left( |v_r(r) - \tilde{v}(r)|, |\partial_r v_r(r)|; \tau \right) r^{m-1} \, dr
\]
\[
- \tau \left( R^{m-1} - (R - \varepsilon)^{m-1} \right),
\]
which is negative and thus contradicts the minimality of \(v_r\). \(\square\)

These results now allow us to calculate the minimizer \(v_r\) by first solving the differential equation (44) for the function \(g_r\) and then calculating \(v_r\) from the differential equation \(g_r(r) \partial_r v_r(r) = v_r(r) - \tilde{v}(r)\) on \(\Omega\). One remaining problem in this approach is that the function \(g_r\) does not need to be continuous, though. Therefore, the solution of the differential equation (44) depends on the position of the discontinuities of \(g_r\). The next section will thus be dedicated to the behavior of this function.

7 Behavior of a Rotational Invariant Minimizer

Let again \(v_r \in BV_c\) be a minimizer of the functional \(\mathcal{G}(\tau, \tilde{v}; \cdot)\), where we still make the Assumption 9 for \(\tilde{v}\). To analyze the behavior of \(v_r \in BV_c\), we will
proceed as indicated at the end of the previous section, namely by investigating the function \( g_\tau \) defined by (81).

We have seen in Lemma 10 that \( g_\tau \) is locally absolutely continuous on every set where it is continuous. We therefore may solve the differential equation (34) on every interval where we know \( g_\tau \) to be continuous.

As a first step, we have to derive estimates for the set of discontinuities of \( g_\tau \). Lemma 10 states that \( g_\tau \) \( \operatorname{sgn}(v_\tau - \tilde{v}) \) is continuous on the set where \( g_\tau^2 \neq 2\tau \). Therefore, \( g_\tau \) can only have discontinuities at points \( r \in (0, R) \) where either \( g_\tau^2(r) = 2\tau \) or \( v_\tau(r) = \tilde{v}(r) \).

**Lemma 12.** Assume that \( I \subset [0, R] \) is an interval such that either \( v_\tau(r) \geq \tilde{v}(r) \) for all \( r \in I \) or \( v_\tau(r) \leq \tilde{v}(r) \) for all \( r \in I \). Then the set \( (\Sigma_\tau \cup \{0\}) \cap I \) consists of at most one element.

**Proof.** We perform the proof in the case that \( \tilde{v}(r) \leq v_\tau(r) \) for all \( r \in I \). The other case can be proven analogously.

Since the minimizer \( v_\tau \) satisfies the Euler–Lagrange equation (36) and \( \partial_y f([v_\tau(r_0) - \tilde{v}(r_0)], |\partial_y v_\tau(r_0); \tau|) = 0 \) for \( r_0 \in \Sigma_\tau \), we see that the equation

\[
\int_0^r |g_\tau(r)| r^{m-1} \operatorname{sgn}(v_\tau(r) - \tilde{v}(r)) \, dr = 0
\]  

(42)

is a necessary condition for \( r_0 \) to be contained in \( \Sigma_\tau \cup \{0\} \). By Item 4 in Lemma 10 the function \( g_\tau(r) \) is not equal to zero and since \( v_\tau(r) = \tilde{v}(r) \) for \( \partial_y v_\tau(r) \neq 0 \) only possible if \( g_\tau(r) = 0 \), we know that \( \tilde{v} < v_\tau \) almost everywhere.

Thus, the integrand in (42) is positive almost everywhere on \( I \). Therefore, there exists at most one element \( r_0 \in I \) for which (42) holds. \( \square \)

**Lemma 13.** Assume that \( I \subset [0, R] \) is an interval such that \( \tilde{v} \) is strictly monotonous and absolutely continuous on \( I \). Then there exists at most one point \( r_0 \in I \) with \( v_\tau(r_0) = \tilde{v}(r_0) \).

**Proof.** Assume that \( r_0 \in I \) satisfies \( v_\tau(r_0) = \tilde{v}(r_0) \). We know from Lemma 12 that the set \( \Sigma_\tau \) is countable. Therefore, by the definition of the function \( g_\tau \), the minimizer \( v_\tau \) solves the initial value problem

\[
g_\tau(r) \partial_y v_\tau(r) = v_\tau(r) - \tilde{v}(r) \quad \text{for almost every } r \in I, \quad \text{and } v_\tau(r_0) = \tilde{v}(r_0) .
\]

This differential equation can be solved explicitly, and we find

\[
v_\tau(r) = \tilde{v}(r) - \int_{r_0}^r \exp \left( \int_s^r \frac{1}{g_\tau(y)} \, dy \right) \partial_y \tilde{v}(s) \, ds .
\]

Since \( \tilde{v} \) is strictly monotonous on \( I \), this shows that \( v_\tau(r) \neq \tilde{v}(r) \) for every \( r \in I \setminus \{r_0\} \).

Before we now analyze the behavior of the absolutely continuous parts of the function \( g_\tau \), we formulate a statement concerning the estimation of the solution of an ordinary differential equation.

**Lemma 14.** Let \( \varepsilon > 0 \) and \( a < c < b \in \mathbb{R} \). Assume that \( F: (a, b) \times \mathbb{R} \rightarrow \mathbb{R} \) is continuous and that \( y, z: (a, b) \rightarrow \mathbb{R} \) are absolutely continuous functions with \( \partial_y y(r) \leq F(r, y(r)) - \varepsilon \) and \( \partial_y z(r) \geq F(r, z(r)) \), for almost every \( r \in (a, b) \).
If \( y(c) \leq z(c) \), then \( y(r) \leq z(r) \) for all \( r \in (c, b) \). Conversely, if \( y(c) \geq z(c) \), then \( y(r) \geq z(r) \) for all \( r \in (a, c) \).

**Proof.** We first consider the case where \( y(c) \leq z(c) \). Let us assume the existence of \( r_1 \in (c, b) \) such that \( y(r_1) > z(r_1) \) and define

\[
0 = r_0 := \max \{ r \in [c, r_1] : y(r) \leq z(r) \} .
\]

Then, in particular, \( y(r_0) = z(r_0) \) and \( y(r) > z(r) \) for every \( r \in (r_0, r_1) \).

Because of the continuity of the functions \( F, y, \) and \( z \), there exists \( r_2 > r_0 \) such that

\[
\partial_r y(r) \leq F(r, y(r_0)) - \varepsilon/2 \leq \partial_r z(r) \quad \text{for every} \quad r \in (r_0, r_2) .
\]

Consequently, it follows that for every \( r \in (r_0, r_2) \)

\[
y(r) = y(r_0) + \int_{r_0}^r \partial_r y(s) \, ds \leq z(r_0) + \int_{r_0}^r \partial_r z(s) \, ds = z(r) ,
\]

which contradicts our choice of the point \( r_0 \). Therefore, \( y(r) \leq z(r) \) for every \( r \in (c, b) \).

In the case where \( y(c) \geq z(c) \), we apply the first part of the assertion to the functions \( \tilde{y}(r) = -y(-r) \), \( \tilde{z}(r) = -z(-r) \), and \( \tilde{F}(r, y) = F(-r, -y) \). □

With the help of Lemma 14, we will in the following construct upper and lower bounds for the function \( g_\tau \).

**Lemma 15.** For every \( r \in (0, R) \), we have \( |g_\tau(r)| \geq g_{\tau,+}(r) \), where \( g_{\tau,+}(r) \) is defined as in (38).

In particular,

\[
|g_\tau(r)| \geq \frac{(m - 1) \tau}{r + (m - 1) \sqrt{\tau} / \sqrt{2}} \quad \text{for every} \quad r \in (0, R) . \tag{43}
\]

**Proof.** Since \( \mathcal{L}^1(\Sigma_\tau) = 0 \) and \( (0, R) = \Omega_\tau \cup \Sigma_\tau \), it follows from Lemma 14 that \( g_\tau \) satisfies for almost all \( r \in (0, R) \) the differential equation

\[
\partial_r (g_\tau^2)(r) = F_\tau(r, g_\tau(r)) \quad \text{where} \quad F_\tau(r, g) = \frac{m - 1}{r} (2\tau - g^2) - 2g . \tag{44}
\]

We remark that (38) implies that \( F_\tau(r, g) \) is negative for \( g \in (g_{\tau,+}(r), \sqrt{2\tau}] \) and positive, in particular, for \( g \in (-\sqrt{2\tau}, g_{\tau,+}(r)) \).

Let us now assume that \( g_\tau(r_0) < g_{\tau,+}(r_0) \) for some \( r_0 \in (0, R) \). Since

\[
\partial_r (g_{\tau,+}^2)(r) < 0 = F_\tau(r, |g_{\tau,+}(r)|) \quad \text{and} \quad \partial_r (g_\tau^2)(r) \geq F_\tau(r, |g_\tau(r)|) , \tag{45}
\]

we may apply Lemma 14 to find that \( |g_\tau(r)| \leq g_{\tau,+}(r) \) for all \( r \in (0, r_0) \). In particular, the function \( |g_\tau| \) is monotonically increasing on \((0, r_0)\). This, together with (38) and the monotonicity of \( F_\tau \) with respect to the second component gives

\[
\partial_r (g_\tau^2)(r) \geq \frac{m - 1}{r} (2\tau - g_\tau^2(r_0)) - 2|g_\tau(r_0)| > 0 \quad \text{for almost every} \quad r \in (0, r_0) .
\]

This inequality, however, would imply that \( \lim_{r \to 0} g_\tau^2(r) = -\infty \), which is impossible. □
Lemma 16. Assume that $g_r$ is continuous on the interval $[a, b]$ for some $a, b \in (0, R)$, and assume that $g_r(a) < 0$. Then $b - a \leq \sqrt{2\tau} - |g_r(a)|$.

Proof. Since, by assumption, $g_r$ is continuous on $[a, b]$, and therefore absolutely continuous by Lemma 10, the differential equation simplifies to

$$\partial_r g_r(r) = \frac{m - 1}{2r g_r(r)} (2\tau - g_r^2(r)) - 1$$

for every $r \in (a, b)$.

Since $g_r(a) < 0$ and, by Lemma 10, $g_r(r) \neq 0$ for all $r \in (0, R)$, the continuity of $g_r$ on $[a, b]$ implies that $g_r(r) < 0$ for all $r \in [a, b]$. Using that the right hand side of (46) is smaller or equal $-1$ for $g_r(r) < 0$, it follows that

$$\partial_r g_r(r) \leq -1$$

for every $r \in (a, b)$, and therefore

$$g_r(r) \leq g_r(a) - r + a$$

for every $r \in (a, b)$.

Since $g_r(r) \in (-\sqrt{2\tau}, 0)$ for every $r \in [a, b]$ (which follows from (46) and the fact that $g_r(r)$ is negative), the inequality gives $b - a \leq \sqrt{2\tau} + g_r(a) = \sqrt{2\tau} - |g_r(a)|$. □

Lemma 17. Assume that $g_r$ is continuous on the interval $[a, b]$ for some $a, b \in (0, R)$, and satisfies $g_r(a) > 0$. Moreover, for $\varepsilon \in (0, 1)$ let

$$g_{r,\varepsilon}(r) := \frac{\tau(m - 1)}{r(1 - \varepsilon)}$$

for every $r \in (0, R)$.

Then,

$$g_r(r) \leq g_{r,\varepsilon}(r)$$

for every $r \in (\sqrt{2\tau}/\varepsilon, b)$.

Proof. On

$$\Gamma_r := \{ r \in (a, b) : g_r(r) \geq g_{r,\varepsilon}(r) \},$$

the solution $g_r$ of the differential equation satisfies

$$\partial_r g_r(r) \leq -\varepsilon - \frac{\tau (m - 1)^2}{2r^2 (1 - \varepsilon)} \leq -\varepsilon$$

for every $r \in \Gamma_r$.

Let $(c, d) \subset \Gamma_r$, then by integration of (50) and using (47), which implies that $g_r(r) \in (0, \sqrt{2\tau})$, it follows that

$$0 < g_r(d) - g_r(c) \leq 2\tau - \varepsilon(d - c).$$

Therefore, an interval in $\Gamma_r$ can have at most length $\sqrt{2\tau}/\varepsilon$.

We further remark that the function $g_{r,\varepsilon}(r)$ satisfies

$$\partial_r (g_{r,\varepsilon}^2(r)) = F_\varepsilon(r, g_{r,\varepsilon}(r))$$

for every $r \in (0, R)$, where $F_\varepsilon$ is defined as in (47). From (47) we know that $\partial_r (g_{r,\varepsilon}^2(r)) = F_\varepsilon(r, g_{r,\varepsilon}(r))$ for almost every $r \in (a, b)$. Lemma 14 therefore implies that $g_r(r) \geq g_{r,\varepsilon}(r)$ for every $r \in (r_0, b)$ in case $g_r(r_0) \leq g_{r,\varepsilon}(r_0)$ holds for some $r_0 \in (a, b)$. □
8 Proof of Theorem \[7\]

If the initial function \(v_0 : \mathbb{R}_{\geq 0} \to \mathbb{R}\) is continuous and strictly monotonous on its support \([0, R]\), the results of Section 6 and 7 are sufficient to prove Theorem \[7\].

We define for \(\tau > 0\) the sequence by \(v^{(0)}_\tau = v_0\) and

\[
v^{(k)}_\tau \in \arg\min \{ G(\tau, v^{(k-1)}_\tau); v \in BV_c \}, \quad k \in \mathbb{N}.
\]

The goal is to show that \(\lim_{n \to \infty} v^{(n)}_{\epsilon/\tau}(r) = v_0(\sqrt{r^2 + 2(m-1)t})\) for every \((r, t) \in \mathbb{R}_{>0}^2\). That is, it approximates the solution of the rotationally invariant mean curvature equation \([11]\).

Proof (of Theorem \[7\]). Because of Lemma \[11\] the functions \(v^{(k)}_\tau\), \(k \in \mathbb{N}\), \(\tau > 0\), are absolutely continuous.

We now show by induction that for every \(\tau > 0\) all the functions \(v^{(k)}_\tau\) are strictly monotonous on \([0, R]\). Thus, let us assume that \(v^{(k-1)}_\tau\) is strictly monotonous on \([0, R]\).

Since \(v^{(k-1)}_\tau(R) = v^{(k)}_\tau(R) = 0\), Lemma \[13\] applied to the interval \([0, R]\) implies that \(v^{(k)}_\tau(r) \neq v^{(k-1)}_\tau(r)\) for every \(r \in [0, R]\). Since the functions \(v^{(k)}_\tau\) and \(v^{(k-1)}_\tau\) are continuous and pointwise different in \((0, R)\), one of them has to strictly lie above the other, i.e.,

\[
\text{sgn}(v^{(k)}_\tau - v^{(k-1)}_\tau) = \text{constant}.
\]

From Lemma \[12\] applied to the interval \([0, R]\), it then follows that

\[
\Sigma_{\kappa, \tau} := \{ r \in (0, R) : |v^{(k)}_\tau(r) - v^{(k-1)}_\tau(r)| \geq \sqrt{2\tau} |\partial_r v^{(k)}_\tau(r)| \} = \emptyset.
\]

Thus from Lemma \[13\] (where \(g_\tau\) is replaced by \(g_{k, \tau}\)), we get that the function

\[
g_{k, \tau}(r) := \frac{v^{(k)}_\tau(r) - v^{(k-1)}_\tau(r)}{\partial_r v^{(k)}_\tau(r)}, \quad r \in (0, R),
\]

is continuous and different from zero. In particular, the last two properties imply that \(g_{k, \tau}\) does not change sign in \((0, R)\). Now, assume that \(g_{k, \tau} < 0\) on \((0, R)\), then from Lemma \[13\] it follows that \(R \leq \sqrt{2\tau} - \limsup_{r \to 0} |g_{k, \tau}(r)| = 0\) by Lemma \[15\]. Thus, we have \(g_{k, \tau} > 0\) on \((0, R)\).

Therefore, the function

\[
r \mapsto \text{sgn}(\partial_r v^{(k)}_\tau(r)) = \text{sgn}(v^{(k)}_\tau(r) - v^{(k-1)}_\tau(r))
\]

is constant and different from zero on \((0, R)\) (cf. \[11\]). This shows that \(v^{(k)}_\tau\) is strictly monotonous.

Moreover, the functions \(g_{\tau, k}\), \(k \in \mathbb{N}\), are absolutely continuous on \((0, R)\) and solve the differential equation \([50]\) which is independent of the functions \(v_{k, \tau}\). Therefore \(g_{\tau, k} = g_\tau\) where \(g_\tau\) denotes the absolutely continuous solution of \([50]\).

For \(\varepsilon > 0\) let \(r > r_{\tau, \varepsilon} := \frac{m-1}{2} \sqrt{2\tau}\). Using the positivity of \(g_\tau\) and \([50]\) and \([50]\) in Lemma \[16\] and Lemma \[17\] respectively, it follows that

\[
\left| -\frac{\tau}{g_\tau(r)} - \frac{r}{m-1} \right| < \frac{r}{m-1} \varepsilon.
\]

20
We define the strictly increasing function

\[ G_{\varepsilon,\tau} : (0, R) \to \mathbb{R}, \quad G_{\varepsilon,\tau}(r) = \int_{r_{\varepsilon,\tau}}^{r} \frac{\tau}{g_{\tau}(y)} \, dy. \]

From the definition 32 of \( g_{k,\tau} \), we find the initial value problem

\[ \partial_{r} v_{\tau}^{(k)}(r) = \frac{1}{g_{\tau}(r)} \left( v_{\tau}^{(k)}(r) - v_{\tau}^{(k-1)}(r) \right), \quad v_{\tau}^{(k)}(R) = 0, \]

for the minimizer \( v_{\tau}^{(k)} \). It follows by variation of constants that

\[ v_{\tau}^{(k)}(r) = \int_{r}^{\infty} \frac{1}{g_{\tau}(s)} \exp \left( - \int_{r}^{s} \frac{1}{g_{\tau}(y)} \, dy \right) v_{\tau}^{(k-1)}(s) \, ds. \]

Substituting therein \( s = G_{\varepsilon,\tau}^{-1}(w_{k} + G_{\varepsilon,\tau}(r)) \), we find

\[ v_{\tau}^{(k)}(r) = \int_{0}^{\infty} \frac{1}{r} \exp \left( - \frac{w_{k}}{r} \right) v_{\tau}^{(k-1)}(G_{\varepsilon,\tau}^{-1}(w_{k} + G_{\varepsilon,\tau}(r))) \, dw_{k}. \]

Using this formula iteratively, we finally get

\[ v_{\tau}^{(k)}(r) = \int_{\mathbb{R}_{>0}} \frac{1}{r} \exp \left( - \frac{1}{\tau} \sum_{j=1}^{k} w_{j} \right) v_{0} \left( G_{\varepsilon,\tau}^{-1} \left( \sum_{j=1}^{k} w_{j} + G_{\varepsilon,\tau}(r) \right) \right) \prod_{j=1}^{k} \, dw_{j}. \]

Substituting now \( z_{\ell} = \sum_{j=1}^{\ell} w_{j}, 1 \leq \ell \leq k, \) and integrating out the variables \( z_{\ell} \) with \( \ell < k \), we are left with (setting \( z = z_{k} \))

\[ v_{\tau}^{(k)}(r) = \int_{0}^{\infty} \frac{z^{k-1}}{\tau^{k}(k-1)!} \exp \left( - \frac{z}{\tau} \right) v_{0} \left( G_{\varepsilon,\tau}^{-1} \left( z + G_{\varepsilon,\tau}(r) \right) \right) \, dz. \]

Choosing \( \tau = t/n \) and \( \varepsilon = \sqrt{\tau} \), it follows from 33 that

\[ \lim_{n \to \infty} G_{\varepsilon,\tau}^{-1}(z + G_{\varepsilon,\tau}(r)) = \sqrt{2(m-1)z + r^{2}} \]

locally uniformly for \((z, r) \in \mathbb{R}_{>0} \times (0, \infty)\). Now we find with Stirling’s formula

\[ \lim_{n \to \infty} \frac{n!}{(n/e)^{n} \sqrt{2\pi n}} = 1 \]

that for every \( r \in (r_{\varepsilon,\tau}, \infty) \)

\[ \lim_{n \to \infty} v_{\ell/n}^{(n)}(r) = \lim_{n \to \infty} \sqrt{\frac{n}{2\pi}} \int_{0}^{\infty} e^{-\left( n-1 \right)(z-1-\log z)} e^{1-z} v_{0} \left( \sqrt{2(m-1)tz + r^{2}} \right) \, dz. \]

The function \( z - 1 - \log z \) in the exponent herein is now positive on \( \mathbb{R}_{>0} \setminus \{1\} \) and has the Taylor expansion

\[ z - 1 - \log z = \frac{(z-1)^{2}}{2} + \sum_{\ell=3}^{\infty} \frac{(1-z)^{\ell}}{\ell} \]

around its minimum point 1. In the limit \( n \to \infty \), only the lowest order term will contribute and so we can write

\[ \lim_{n \to \infty} v_{\ell/n}^{(n)}(r) = \lim_{n \to \infty} \sqrt{\frac{n}{2\pi}} \int_{0}^{\infty} e^{-\left( n-1 \right)(z-1)^{2}/2} e^{1-z} v_{0} \left( \sqrt{2(m-1)tz + r^{2}} \right) \, dz. \]

21
Because the functions \( \frac{1}{2\sqrt{\pi} n^{(n-1)/2}} \) converge for \( n \to \infty \) to the \( \delta \)-distribution at the point 1, it follows that

\[
\lim_{n \to \infty} v^{(n)}_{t/n}(r) = v_0\left(\sqrt{2(m-1)t + r^2}\right).
\]

This completes the proof. \( \Box \)

9 Conclusion

We have introduced a concept of gradient flows generated by non-convex energy terms and distance measures. As in standard semi-group theory, the flow is defined by iterative minimization of a functional composed by the distance measure and the scaled energy. Since the existence of minimizers, however, is strongly related to convexity, it is necessary to use generalized minimizers instead, which are defined by relaxation.

The main motivation for considering non-convex flows are geometric PDEs, which cannot be treated by a standard semi-group theory. We have shown that our theory applies to mean curvature motion with special initial data. From the calculations in this paper it seems that the identity also holds for more complex rotationally invariant data; however, the identity could not be established rigorously. We have demonstrated that our notion of solution can serve as a solution concept of the mean curvature motion for arbitrary integrable initial data, for which, up to now, no solution concept exists.
