

# Performance of the GAP-function Normalizer and an attempt of its improvement II

Izumi Miyamoto

University of Yamanashi

[imiyamoto@yamanashi.ac.jp](mailto:imiyamoto@yamanashi.ac.jp)

Let  $\Omega = \{1, 2, \dots, n\}$ .

Let  $G$  and  $H$  be permutation groups on  $\Omega$ .

The normalizer of  $G$  in  $H$  is defined by

$$\text{Norm}(H, G) = \{ h \in H \mid h^{-1}Gh = G \}.$$

Suppose  $H = \text{Sym}(n) = \text{SymmetricGroup}(\Omega)$ .

GAP4 - Groups, Algorithms, Programming (version 4)- a System for Computational Discrete Algebra has a special function "DoNormalizerSA" for such cases.

If  $G$  is imprimitive and only one block system of block length  $l$ , for instance,  $l = 2$ ,

then  $\text{Norm}(\text{Sym}(n), G) \subseteq W$ ,

where  $W = \text{WreathProduct}(\text{Sym}(n/2), \text{Sym}(2))$ .

DoNormalizerSA invokes NormalizerParentSA to compute  $W$  and then computes

$\text{Norm}(W, G)$  instead of  $\text{Norm}(\text{Sym}(n), G)$ .

Even if  $G$  is primitive, we have such a subgroup as above.

Proposition.('97)

If  $G$  is transitive, then the normalizer of  $G$  is contained in the automorphism group of the association scheme  $A$  formed by  $G$ .

So  $\text{Norm}(\text{Sym}(n), G) = \text{Norm}(\text{Aut}(A), G)$ .

The wreath product  $W$  appears as the automorphism group of a typical association scheme.

Example: the relation matrix of an association scheme consisting of the orbits of  $G$  on  $\Omega \times \Omega$

$$A = \left( \begin{array}{cccccccccccc} \overbrace{0 & 1 & 1 & 1 & 1 & 1}^{\Omega} & 2 & 2 & 2 & 2 & 2 & 2 \\ 1 & 0 & 1 & 1 & 1 & 1 & 2 & 2 & 2 & 2 & 2 & 2 \\ 1 & 1 & 0 & 1 & 1 & 1 & 2 & 2 & 2 & 2 & 2 & 2 \\ 1 & 1 & 1 & 0 & 1 & 1 & 2 & 2 & 2 & 2 & 2 & 2 \\ 1 & 1 & 1 & 1 & 0 & 1 & 2 & 2 & 2 & 2 & 2 & 2 \\ 1 & 1 & 1 & 1 & 1 & 0 & 2 & 2 & 2 & 2 & 2 & 2 \\ 2 & 2 & 2 & 2 & 2 & 2 & 0 & 1 & 1 & 1 & 1 & 1 \\ 2 & 2 & 2 & 2 & 2 & 2 & 1 & 0 & 1 & 1 & 1 & 1 \\ 2 & 2 & 2 & 2 & 2 & 2 & 1 & 1 & 0 & 1 & 1 & 1 \\ 2 & 2 & 2 & 2 & 2 & 2 & 1 & 1 & 1 & 0 & 1 & 1 \\ 2 & 2 & 2 & 2 & 2 & 2 & 1 & 1 & 1 & 1 & 0 & 1 \\ 2 & 2 & 2 & 2 & 2 & 2 & 1 & 1 & 1 & 1 & 1 & 0 \end{array} \right) \left. \vphantom{\begin{array}{c} \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \end{array}} \right\} \Omega$$

$$\text{Aut}(A) = \text{WreathProduct}(\text{Sym}(6), \text{Sym}(2))$$

Example: the relation matrices of association schemes

$$A = \begin{pmatrix} 0 & 1 & 1 & 2 & 2 & 2 \\ 1 & 0 & 1 & 2 & 2 & 2 \\ 1 & 1 & 0 & 2 & 2 & 2 \\ 2 & 2 & 2 & 0 & 1 & 1 \\ 2 & 2 & 2 & 1 & 0 & 1 \\ 2 & 2 & 2 & 1 & 1 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 1 & 2 & 3 & 3 & 3 \\ 2 & 0 & 1 & 3 & 3 & 3 \\ 1 & 2 & 0 & 3 & 3 & 3 \\ 3 & 3 & 3 & 0 & 1 & 2 \\ 3 & 3 & 3 & 2 & 0 & 1 \\ 3 & 3 & 3 & 1 & 2 & 0 \end{pmatrix}$$

$\text{WreathProduct}(\text{Sym}(3), \text{Sym}(2))$  forms  $A$ .

$\text{WreathProduct}(\text{Cyc}(3), \text{Sym}(2))$  forms  $B$ .

Both groups have only one same block system.

Block system cannot distinguish  $A$  and  $B$ .

We would like to show two algorithms

Algorithm A-I and Algorithm A-II,

which only work on transitive groups now.

We will not use association schemes but only Wreath-Products in both Algorithms. Our programs are short and consist of 100 lines or so.

We use a backtrack method to compute the automorphism groups of association schemes. So it is not an easy computation, but it is much easier than to compute normalizers directly in some cases.

If  $G$  is transitive, we can also use the following lemma.

Lemma.('00)

Let  $K$  be a permutation group on  $\Omega$ . Let  $F$  be a tuple  $[p_1, p_2, \dots, p_r]$  of points in  $\Omega$  and let  $G^i$  be the stabilizer of the subset  $[p_1, p_2, \dots, p_i]$  of  $F$  as a tuple in  $G$  for  $i = 1, 2, \dots, r$ . Let  $I^i$  be the group of isomorphisms of the system of association schemes of  $G^i$  on  $\Omega \setminus [p_1, p_2, \dots, p_i]$ . Set  $I^0 = I$ ,  $G^0 = G$  and set  $I^{\{0..i\}} = I^0 \cap I^1 \cap \dots \cap I^i$ . Suppose that  $G^i \cap K$  is transitive on the orbit of  $I^{\{0..i\}} \cap K$  containing the point  $p_{i+1}$  for  $i = 0, 1, \dots, r - 1$ . Then the normalizer of  $G$  in  $K$  is generated by  $G \cap K$  and the normalizer of  $G$  in  $I^{\{0..r\}} \cap K$ .

$K$  in Lemma is used instead of  $Sym(n)$  in  $\text{Norm}(Sym(n), G)$ .

$K$  may be WreathProduct or  $Aut(A)$ .

Lemma says

if  $K$  and  $G$  have a same orbit, containing  $p$ ,  
then  $\text{Norm}(K, G) = G\text{Norm}(K_p, G)$ .

Note that

$$\text{Norm}(K_p, G) = \text{Norm}(\text{Norm}(K_p, G_p), G).$$

Suppose furthermore that

if  $K_p$  and  $G_p$  have a same orbit, containing  $p'$ ,  
then  $\text{Norm}(K_p, G_p) = G_p\text{Norm}(K_{p,p'}, G_p)$ .

$$\text{Norm}(K_{p,p'}, G_p) = \text{Norm}(\text{Norm}(K_{p,p'}, G_{p.p'}), G_p).$$

$$\text{Norm}(K, G) = G\text{Norm}(\text{Norm}(K_{p,p'}, G_p), G).$$

Or something else happens so that

$$\text{OrbitLengths}(G_p) = [l_1, l_2] \quad (l_1 \neq l_2).$$

Then  $\text{Norm}(K_p, G_p) = \text{Norm}(K_p \cap D, G_p)$ ,

where  $D = \text{DirectProduct}(\text{Sym}(l_1), \text{Sym}(l_2))$ .

(  $D$  is computed by NormalizerParentSA. )

So various heuristics arise from this computation.

From these arguments we have

Algorithm A-I which uses a lot of heuristics.

Suppose that

$B^G$  is the only one block system of  $G$  of  $l = |B|$ .

Here  $G_B$  is the setwise stabilizer of  $B$  in  $G$ .

SubgpConjSymmgrp, another GAP special function, which computes a conjugating element between two subgroups in a symmetric group considers these actions  $\bar{G}$  and  $G_B|B$ .

For computing normalizers, let

$$H = \text{Norm}(\text{Sym}(l), G_B|B) \text{ and } K = \text{Norm}(\text{Sym}(n/l), \bar{G}).$$

Then

$$\text{Norm}(\text{Sym}(n), G) \subseteq \text{WreathProduct}(H, K)$$

We apply this argument recursively. We use Lemma on this  $\text{WreathProduct}(H, K)$  with some heuristics.

This gives Algorithm A-II

# Experiment

$\text{Norm}(\text{Sym}(n), \text{TransitiveGroup}(n, k))$

of degree  $n$ ,  $20 \leq n \leq 30$ .

	number of groups

# DoNormalizerSA and AutomorphismGroupPermGroup

applied to

some intransitive groups of degree  $n - 1$

$\text{Norm}(\text{Sym}(n - 1), \text{Stabilizer}(\text{PrimitiveGroup}(n, k), n))$

( in seconds )

$n$	$k$	DoNorm	AutPerm
81	123	37	0.2
100	3	77	0.3
105	9	12	0.3
112	1	19652	0.4
120	12	46	0.5

$G = \text{Stabilizer}(\text{PrimitiveGroup}(81, 123), 81)$

$\text{OrbitLengths}(G) = [40, 40]$

$W = \text{WreathProduct}(\text{Sym}(40), \text{Sym}(2))$

It took 23 seconds for  $\text{SmallGeneratingSet}(W)$ .

$G = \text{Stabilizer}(\text{PrimitiveGroup}(112, 1), 112)$

$\text{OrbitLengths}(G) = [81, 30]$

$W = \text{DirectProduct}(\text{Sym}(81), \text{DoNorm}(\text{Sym}(30), G^{O_2}))$

$G^{O_2} \cong \text{TransitiveGroup}(30, 1019)$

It took 11854 seconds for  $\text{DoNorm}(\text{Sym}(30), G^{O_2})$ .

It took 0.2 seconds for  $\text{DoNorm}(\text{Sym}(81), G^{O_1})$ .

$G$  is faithful on both orbits.

Example:  $\text{Norm}(H, G)$ ,  $H \neq \text{Sym}(n)$

$H = \text{WreathProduct} \not\subseteq G = \text{TransitiveGroup}(n, k)$

time range by $\text{DoNorm}(\text{Sym}(n), G)$	$30\text{min} \leq * \leq 1\text{hour}$
number of groups	117
total time for $\text{DoNorm}(\text{Sym}(n), G)$	4962min
total time for $\text{Norm}(H, G)$	1162min

Some computing times for  $\text{DoNorm}(\text{Sym}(n), G)$  and

$\text{Norm}(H, G)$  ( in seconds )

$n$	$k$	$\text{DoNorm}(\text{Sym}(n), G)$	$\text{Norm}(H, G)$
30	2173	3565	6052
30	2256	2064	2580
30	2548	2714	3200
30	2560	2704	3311
30	4644	1978	4230

Remark : Computational complexity of Normalizer

L.M. Luks and T. Miyazaki

Polynomial-time normalizers for permutation groups with restricted composition factors. (ISSAC2002)

$\text{Norm}(H, G)$

If  $H$  has restricted composition factors, then Norm is  $\mathcal{P}$ .

This algorithm seems far from actual computation now.
